THE CLINICAL HISTORY AND RECOGNITION
OF TUBERCULOUS MENINGITIS

HENRY KOPLIK, M.D.

NEW YORK

The symptomatology of tuberculous meningitis when well inaugurated is certainly characteristic and can offer very few difficulties to those who have followed any number of these cases through an illness. There has always been, however, a desire on the part of clinicians to recognize the disease in its incipient stage, or as the books call it, the first stage of the disease. So important a matter is this to the practitioner that the consultant is often confronted in his daily work with the important problem as to whether a certain symptom complex can definitely be said to be indicative of tuberculous meningitis. There was a discussion of this matter in a meeting of the Pediatric Society in 1890. At this time stress was laid on the fact that the early diagnosis of tuberculous meningitis was not only difficult but in some cases well nigh impossible. Such symptoms as persistent vomiting, irregularity of pulse and of respiration and apathy certainly were indefinite guides to an early diagnosis. To day, however, with our advanced clinical methods, we are able to approach a case with greater certainty than was possible in past years.

During the past six years I have been fortunate in having under direct observation no less than fifty-two cases of tuberculous meningitis in my hospital service. These cases were admitted at different periods of the disease, some coming to me on the second day of pronounced symptoms, others as late as the sixth week of the disease, the average duration of the disease before admission to my service being one week.

In all the cases which I will utilize for this paper the diagnosis was fixed clinically and confirmed either by postmortem examination, lumbar puncture or by animal experimentation. An opportunity is thus offered to consider an accurate symptomatology of cases which have been absolutely proved to be of a tuberculous nature. In all a tentative clinical diagnosis was at first made before the lumbar puncture was considered. In other words no case was punctured unless there was a suspicion, at least, of meningitis, primarily that of the tuberculous variety.

AGE OF THE PATIENT

The oldest case coming under our observation was ten years, the youngest six months. Eleven were under one year of age. Thirty-four per cent (18 cases) were under two years of age, and thirty per cent, (16) were under four. Thirty-four (18) were four years of age and over. The average of all the cases was four years and four months.

I have studied these cases first as regards the mode of onset, the condition of the nervous system, as evinced in rigidity of the neck, the Kernig symptom, the Babinski reflexes, general reflexes, the MacEwen sign, hyperesthesia, condition of the facial muscles and those of the eyes, the breathing, as to rhythm whether regular or not, the condition of the fundus of the eye, that of the blood, whether a leucocytosis was present or not, and the results obtained by lumbar puncture. Incidentally, also, the course of the temperature, the complications and the presence of eruptions.

MODE OF ONSET

The mode of onset in tuberculous meningitis has always been a matter for careful study and consideration, and there are cases recorded in the literature in which the mode of onset of tuberculous meningitis closely resembled that of cerebro-spinal meningitis of the epidemic type. Osler records a case in which the onset was sudden and in which the fatal issue occurred within six days.

In all my cases old or young, I have never met an instance of such a rapid and lethal course of the disease. The nearest approach to such a rapid onset is the following.

Patient—Male, aged 10½ years, family history negative.

Past Illness—Measles when 1 year old and diphtheria (?) at 4. Right arm fractured three years ago. No history of ear disease or glandular enlargement, no cough, night sweats nor hemoptysis had been struck on the nose four weeks previously with a very hard snowball. Nose became very much swollen and red, and was apparently in normal condition again in about a week.

Present Illness—This began one week before the child was seen with feeling of lassitude, loss of appetite and headache. On the night of onset of illness vomited once, projectile in character. Mother said there had been no fever and strabismus until past twenty-four hours. No chill or convulsions, but constant severe frontal headache without delirium. Pain in nape of neck since day previous but mother did not notice rigidity. Photophobia had been marked since onset. Bowels had been markedly constipated all week, and there had been some abdominal pain. Urination was normal.

Physical Examination—This was made on January 27. General condition good, well nourished, mental condition not apathetic, child answered questions intelligently. Marked hyperesthesia causing child to resist interference. The MacEwen sign was absent, delayed tactile cerebrals, erythematous flush over lower thorax, abdomen and thighs anteriorly. Larynx, thyroid and spine negative. Finger tips showed slight cyanosis, no clubbing. Neck showed marked rigidity.

Eyes. Pupils equal, react to light and to accommodation. Marked internal strabismus of right eye, slight internal strabismus of the left, no petechiae, but slight injection of conjunctiva, no facial paralysis.

Lars and mastoids were negative.

Mouth. Tongue moist, heavily coated, teeth and gums in good condition, throat congested. No herpes, but a fissure at left oral angle.

Lymph nodes Postcervical, axillary, inguinal and left epitrochlear nodes were palpable

Lungs Moderate infra and supra clavicular retraction—more marked on right side, expansile lower is good, anterior negative, posterior dullness at apex with a few sibilant râles, prolonged respiration

Heart Upper border at third rib, right border at r b of sternum, left border at nipple line, apex beat visible and palpable in fifth space, outside of the nipple line, no precordial bulging, action slightly irregular, slight accentuation of first sound at apex, systolic murmur over both basic orifices, moderate accentuation of second pulmonic sound

Pulses, Equal, slightly irregular, full, moderate force No thickening or tension

Liver Fourth space, sixth space to one finger below free border, not palpable

Abdomen Distended, tympanitic, except in hypogastrium, where it was dull, no fluid wave, left kidney palpable, ascending colon too full for satisfactory palpation of right kidney Spleen observed by tympany, not palpable

Extremities Patellar reflex present, Kernig present on both sides, no clonus, no Babinski, cremasteric reflexes on both sides and umbilical reflex present

Genitals Both testes descended, right inguinal being large, no impulse on coughing

Rectum Negative

January 30 Patient was quite rational for past twenty four hours; Kernig persisted in spite of fall of temperature There was considerable rigidity of neck and strabismus was still present He did not pass into the intervals of delirium which were previously present and took his nourishment well, hyperesthesia was marked, slept well

February 1 From time of admission patient had a moderate continuous fever, with slight morning and evening variation He was conscious, but lapsed frequently into mild delirium, did not complain of headache and did not vomit The meningeal signs were practically unchanged, respirations were markedly irregular, the white blood cells, 15,800

February 4 In the past few days condition had become poor, patient was more stuporous, but still conscious when spoken to, no longer complained of headache or pain On February 3 temperature rose to 103.8, the fever generally had been high and continuous, internal strabismus was more marked and there was flattening of right side of face, the mouth was drawn to left side There was marked rigidity, but no opisthotonus, Kernig sign was more marked on left side and there was no Babinski Marked tache cérébrale, very slight twitching of the arm

February 5 Slight improvement in patient's mental condition, he answered when spoken to, but speech was very indistinct and low, right facial palsy persisted, respirations were audible and the tongue had a tendency to fall back, since the afternoon previous patient had difficulty in swallowing Double optic neuritis was present and around the right disc were seen several hemorrhages

February 6 Temperature, 99.4, Kernig sign present (10 a. m.) Lumbar puncture was performed and about 50 c.c. clear fluid were withdrawn.

Pathologic Report—Cytology Polynuclears, 10 per cent., lymphocytes, 90 per cent Spreads Tubercle bacilli Culture Negative. Albumin Increased. Sugar Negative

On admission this case impressed the writer as being one of cerebrospinal meningitis of the epidemic variety on account of the marked rigidity, hyperesthesia, the activity of the delirium, and the positiveness of the assertion of the parents of the sudden onset When lumbar puncture was made the error was proved

In all classes of society parents do not always observe accurately, and it is possible in all these cases in which the onset is said to be abrupt that there has been an indefinite period preceding the pronounced symptoms in which the patient did not feel entirely well Children do not complain of mild symptoms as a rule They are so anxious to be about and in the open that a slight head-

ache and any indisposition, or a mild degree of fever would scarcely be noticed Hence I must regard a data as to sudden onset in the majority of cases of tuberculous meningitis as of doubtful nature.

Most mothers, it is true, are excellent clinical observers of their own children if they are allowed the time to observe Among the poorer classes such time is not at their disposal, and the result is that the initial period of the disease is lost to observation One mother may notice the insidious change in the conduct of her child whereas another mother would scarcely have the time to see these changes, being too much occupied with her other duties to observe It may be said here that in 86 per cent of the cases, that is in 42 cases, a positive history of insidious onset was given The mother could tell us that the infant or child was not quite well, complained (if it was old enough) of slight headache and vomited from time to time In those cases which came to us early, as in the second day of the disease, there was no history of vomiting Generally there was a slight febrile movement, or the child was irritable, refused to nurse, or the mother simply noticed that the little one was not itself It is only in those cases that came to us after the disease had lasted a week that there was a history of vomiting In some of the cases among the older children there was complaint of pain and headache, in other cases there may have been a convulsion As a rule, however, convulsions were not present until the disease had lasted fully twelve days or two weeks

In the remaining cases (10) there was lacking a history of slow onset. One mother, bringing a child of six and a half years of age with a duration of illness of six weeks, thought that the disease began suddenly with fever, chill and headache In our history there were two other cases of seven and eight years, respectively, in which the mother thought the disease began suddenly with vomiting and headache Another case of two years, in which the mother asserted that vomiting and convulsions suddenly set in In all these cases the house physician could not obtain a positive history of sudden onset, so that the child may have been ill for a week previous to the vomiting and convulsions, with slight malaise, and a busy mother, distracted by household cares, may not have noticed that the child was ailing Therefore, confirming what is generally known of this disease, the onset in the majority of the cases that we could trace in the reliable histories was slow and insidious

NERVOUS SYSTEM

The condition of the nervous system is of special interest in all these cases Of greatest importance is the presence or absence of rigidity There are some cases of tuberculous meningitis in which such rigidity is absent at all periods of the disease Fourteen of our cases were of such a nature, in other words, 27 per cent. In some cases opisthotonos and rigidity, if present, as a rule were slightly marked, that is, the head was movable almost to a normal degree Rigidity in all cases is tested simply as a child lies in bed, the head is raised, and if with the head the body is raised also, rigidity is considered to be present. In some cases a rigidity may only mean a stiffness of the neck, such a symptom will be easily recognized by any intelligent physician In no case did rigidity appear before the first week, and in this respect tuberculous meningitis differs markedly from the meningitis of the acute cerebrospinal type, that is, especially of the epi-

demic form, in which rigidity is the rule and opisthotonos not infrequent

Patients with tuberculous meningitis lie stupid, they do not notice what is going on and do not react to irritation as do cases of meningitis of the epidemic form. Hyperesthesia, either of the surface or the senses, as a rule, is absent or slightly marked. Such was the condition in 90 per cent of my cases. In this respect tuberculous meningitis differs distinctly from that of the epidemic cerebrospinal form, in which hyperesthesia is the rule, not only from the onset but throughout the disease.

Much stress has been laid by various authors on the diagnostic value of the Kernig symptom in cases of meningitis, but it must be said that though we have found the Kernig symptom present in 22 of our 52 cases, it was absent in others, and does not aid the ultimate diagnosis of the disease. In fact, clinically, there are other symptoms which are more significant in the cases of tuberculous meningitis, which we have studied, than the Kernig symptom.

Strange to say, the Babinski reflex in children over two years of age is a much more valuable guide, clinically, as to the nature of the meningitis, if meningeal symptoms are present, than the Kernig phenomenon. In our 52 cases of tuberculous meningitis the Babinski reflex was present in 23 cases, and, if present, to my mind, it is presumptive evidence of the tuberculous nature of the disease, as compared to what is noted in the acute suppurative forms of meningitis. I have only found it present in exceptional cases of cerebrospinal meningitis of the epidemic type or of the suppurative form. The general reflexes were present in most of our cases of tuberculous meningitis, except in those where the patients came to us very late in the disease, in these they were abolished.

SKIN ERUPTIONS

The presence or absence of herpes or skin eruptions does not help us in the diagnosis of tuberculous meningitis, inasmuch as their absence is the rule and their presence is very inconstant. Certainly the presence of herpes and petechiæ are characteristic of cerebrospinal meningitis of the epidemic form, and at the outset of meningitis the presence of petechiæ speaks in favor of the epidemic form of the disease and will aid us in excluding the tuberculous forms. Herpes are seen in tuberculous meningitis, and if present are due possibly to a complicating neuritis or pneumonia.

Some of the minor points of diagnosis, such as the *tâche cérébrale*, which is present in most cases, not only of meningitis but in affections accompanied by cerebral symptoms is of very little value and useless as an aid to diagnosis.

The pulse also as to its frequency and quality is of questionable value in the diagnosis of tuberculous meningitis. It is true in the acute suppurative forms of meningitis, especially cerebrospinal meningitis of the epidemic type, the pulse is quite rapid. But there are periods in this disease where the pulse may not only be slow but irregular, as in tuberculous meningitis, so that we can scarcely conclude from the frequency and quality of the pulse anything of diagnostic import.

The respirations in tuberculous meningitis are irregular in rhythm, sighing in character and in some cases take that form called Cheyne-Stokes. The same form of respiration is seen in meningitis of various types, so that we can scarcely consider the respiration, its char-

acter and frequency, as of any value in concluding as to the specific form of meningitis present.

Vomiting in tuberculous meningitis occurs at a time when the ventricles begin to be distended with fluid. It is rarely persistent. In a few cases of my series there was a history of unusual vomiting, but in no case could it be said that this vomiting formed a leading feature of the disease, nor did it attract attention to any extent, and its presence had to be ascertained by close questioning of the parents or friends of the patients. As a rule vomiting occurs once or twice in tuberculous meningitis. It is certainly not persistent. After the condition of hydrocephalus is well established vomiting may be repeated at frequent intervals.

TEMPERATURE.

Of great utility is an exact observation of the course of the temperature at an early period of the disease. The absence of fever or a persistently low temperature with some of the cerebral symptoms detailed in this paper is very strong evidence of the presence of tuberculous meningitis. In those cases of tuberculous meningitis in which the temperature ranges as high as 104 and 105 we are either in the presence of a complication or in the period of the disease close to the exitus. As a rule, toward the exitus the temperature rises.

PARESIS

The presence or absence of localized paresis of the face or extremities is only useful as an aid to diagnosis toward the close of the disease. Being absent at an earlier period of the affection, it is of no value at this time and only becomes apparent when the accumulation of fluid in the ventricles and subarachnoid space is considerable. Pareses having once been established, their evanescent character is of great import. It is not infrequent to find that left facial paresis one day will give way to a paresis on the right side of the face the next. This is quite characteristic of tuberculous meningitis, and can only be explained by the fact that some of these pareses are caused by pressure on the nerves at the base of the brain and that this pressure is apt to change from time to time, varying with the amount of distension of the lateral ventricles by fluid.

BLOOD

The presence or the absence of a leucocytosis or we may say, the presence of a leucopenia, has long been considered as a very valuable adjunct to diagnosis in tuberculous meningitis, as in tuberculous processes elsewhere. In 35 cases of the series of 52 that we have studied the leucocyte count was lower than 20,000 to the cmm at certain periods of the disease. In the remaining cases the leucocyte count varied from 20,000 to 29,000 white blood cells to the cmm. In no case did the leucocyte count exceed 29,000 to the cmm except in those cases in which a blood count was taken in the presence of impending death. In such cases the leucocyte count was found to be 32,000 to the cmm and in one case 39,000. It may be said therefore that leucopenia is presumptive evidence of a tuberculous process. We can not conclude positively in the absence of the opposite condition that no tuberculous process is present.

The lowest leucocyte count of any tuberculous case of the 52 utilized in this paper was 7,200. The count of the blood therefore, as far as the leucocyte count is concerned does not reveal anything pathologic of the disease.

THE CONDITION OF THE EYES

Of great interest in this form of meningitis, as compared to other types of the disease, is the condition of the fundus. The eyes of all our cases of meningitis were examined by Dr Gruning or his assistants in the eye service of the hospital and he examined 46 of our cases of tuberculous meningitis. Of these cases the fundus was normal at the outset of 34 per cent of the cases. In 66 per cent of the cases there was some change in the disc, varying from optic neuritis to the presence of tubercle in the tissue of the choroid. In some cases the disc was simply swollen and indistinct in its margin, in other cases the veins were distended. The interesting fact is that choroid tubercle was present in 9 cases of the 46 examined as early as the second day of duration of the active symptoms of the disease, that is from the first to the sixth week of the disease. These tubercles in the choroid may be discovered at any period of the affection. I have seen them present in the fundus when the cerebral symptoms were insignificant.

As distinguished from this condition of the fundus in tuberculous meningitis, we may mention the fact that in meningitis of other types, especially in the cerebrospinal meningitis of the epidemic type, the fundus in the majority of the cases shows very little, if any, change throughout the disease. The presence of optic neuritis in cerebrospinal meningitis is exceptional; it certainly is not as frequent as in tuberculous meningitis.

PERCUSSION OF THE SKULL

Of great value at the outset of tuberculous meningitis, where the symptoms are rather equivocal and while the child is still apparently conscious and plays during part of the day, is percussion of the skull. MacEwen was the first to apply this method of diagnosis, and his cases were mostly those of tumor or abscess at the base of the brain pressing on the veins in this locality and thus causing hydrocephalus. Although he investigated a large variety of cases in children and applied percussion of the skull to them in making a diagnosis of distension of the ventricles by fluid, he did not devote his attention to any one disease specially. In my studies of tuberculous meningitis and meningitis of the epidemic cerebrospinal type I have followed out percussion of the skull according to the method of MacEwen. This method I have described elsewhere, and I have applied it to healthy children in order to determine at what age this sign could be relied upon as an abnormal manifestation in children. That is, at what period of life the tympanic note obtained by percussion over the lateral ventricles could aid us in a diagnosis of hydrocephalus. It may be said that beyond the age of two to two and one-half years, when the skull is completely ossified, this sign should not be present if there is a normal conformity of the head and if there has been no pre-existing hydrocephalus.

In 34 of the 52 cases which I have studied of tuberculous meningitis I have found that a percussion of the head at a very early period of the disease following MacEwen's method as to the position of the patient, which should be upright with the head slightly inclined to one side, the percussion being performed at the pterion, is a most valuable means of discovering the presence of hydrocephalus interna in tuberculous meningitis.

I recall the case of a girl of fourteen, who had been ill only one week, complained of headache, felt tired, with a tendency to be drowsy at times of the day, at

others she was quite bright. The patient had absolutely no fever for eight days. When I saw the patient she was apparently asleep in bed, could be easily aroused, and when aroused recognized her physicians. There was very little rigidity of the neck, although Kernig's sign was present. Percussion of the skull cap in this case, according to the lines marked out by MacEwen, gave a tympanic note over the pterion, and on this I unhesitatingly made a diagnosis of hydrocephalus, to the astonishment of the physician, who thought he had to deal with a case of hysteria, knowing, as I did, that hysteria could certainly not produce a percussion note of tympanic character over the situation of the lateral ventricles of the brain.

This case was subsequently seen by other consultants, who were inclined at first to disagree with the diagnosis of tuberculous meningitis. A week subsequent to my examination the patient died with the classical symptoms of tuberculous meningitis, the other consultants agreeing in the diagnosis. Percussion of the skull at an early period of tuberculous meningitis is certainly one of the most valuable aids in diagnosis.

LUMBAR PUNCTURE

The fluid obtained by lumbar puncture in cases of meningitis of the tuberculous and other varieties has been studied as to the pressure under which it is contained in the ventricles and in the subarachnoid space (Quinke, Ricken, Falkenheim, Pfundler). As to its appearance, speaking now of tuberculous meningitis, (Lichthem, Schiff, Brenner), as to its density (Achord and Loeper), its cryoscopy (Widal and Sicard), its chemical properties (Gautier, Achard), its toxicity (Widal, Sicard, Lensé), and its agglutinating properties in case of the tubercle bacillus (Hawthorn).

All above directions of study are of great value scientifically and have their important remote bearings. Clinically, the physician at the bedside is not equipped to carry out methods which will give him details as to the above, and we must seek practical results rather from an examination of the bacterial and cellular content of the fluid obtained by lumbar puncture. Inoculations in animals and cultures are also tedious, and though certain as far as animal experiment is concerned, 100 per cent of the cases being positive (Widal and LeSourd), the physician seeking immediate results must resort to an examination of the centrifuged fluid by stain for the tubercle bacillus. Even here one would think that uniform results would be obtained. Marfan found bacilli only in exceptional cases, Heubner had similar results. Friedjung found them frequently, Kohts in 50 per cent of the cases, Pfundler in 70 per cent of the cases, Schlawy and Manicatide in 16 of 19 cases. Lichthem found the tubercle bacillus always present. Pfundler found the bacilli more readily in the later periods of the disease (75 per cent) than in the early stages (33 per cent). Our own cases seem to show that though in the later stages of the disease the bacilli may be more abundant, their presence in the early stages can be verified by patient search of the fluid.

I have intimated in this paper that in 52 cases of tuberculous meningitis I have been able to make a diagnosis clinically in the majority of cases without the aid of what may be considered our most valuable precise diagnostic method, that of lumbar puncture. In other words, lumbar puncture in the majority of my cases was performed after the diagnosis of tuberculous meningitis had been made as a possible condition. The

fluid withdrawn was then examined as to the presence or absence of tubercle bacilli.

I have left this procedure for more detailed consideration because I wish to show that it is possible with moderate certainty, to make a diagnosis of tuberculous meningitis early in the disease from a consideration of clinical methods which I am describing. No case of tuberculous meningitis should be positively considered as such until it had been studied for some length of time, a few days at least, because first appearances are always deceptive, and such a diagnosis once made is quite a serious blow to the friends of the patient. We should be exceedingly cautious, therefore, not to fix the diagnosis of tuberculous meningitis without the aid of an extended previous study of the case either through another physician or our own study at the bedside. Once having made a diagnosis of its possible presence, we may then proceed, and then only, to make a lumbar puncture in order to fix the diagnosis beyond equivocation.

I have never made a lumbar puncture in these cases without feeling that a meningitis of some kind was present. In other words, lumbar puncture should be resorted to only as a means of confirming or excluding the presence of a disease whose prognosis is hopeless. In this respect is it valuable to the friends of the patient? It is in tuberculous meningitis, especially, that much confusion has resulted on account of the various data given in different clinics as the result of the careful examination of the fluid obtained by puncture. Personally we consider that lumbar puncture is an absolutely certain means in a majority of cases of confirming the diagnosis of tuberculous meningitis, for we feel that in the majority of the cases tubercle bacilli can be found in the puncture fluid if care and diligence be exercised. The fluid, of course, must be drawn so as to be free of the mixture of blood, and a certain amount of experience is necessary to succeed in this respect. It must then be carefully centrifuged in order to examine the sediment. During the past five years we have examined 66 successive cases, of which two were doubtful, diagnosed clinically as tuberculous meningitis with a view of detecting tubercle bacilli in the puncture fluid. In 42 cases we have found the tubercle bacilli. I may say here that one man alone examined all fluids, and it is due to his patience that we have been able to prove that a diagnosis is possible in the majority of cases from the examination of the puncture fluid. Dr. Bernstein of the Mt. Sinai Hospital staff has devoted his time to this study, and a more detailed account of this work can be found in a monograph recently published by him.

In previous years we have not been successful in obtaining positive results in the examination of the puncture fluid and we feel that this has been due to a faulty technic. In the years 1904 to 1906 29 cases diagnosed as tuberculous meningitis revealed tubercle bacilli in the fluid of puncture in 24. In two of these 29 cases a diagnosis was not fixed positively at the time of puncture. Thus in 24 of 27 cases punctured tubercle bacilli were found as confirming the clinical diagnosis. In those cases, it may be mentioned incidentally, in which tubercle bacilli were not found in the puncture fluid, the laboratory was kind enough to inject this fluid into guinea-pigs, and in this way secured a positive result. This however, was in an early period of our studies on the disease.

Thus it may be said that, given a case which clinically

leads us to surmise the presence of tuberculous meningitis, a lumbar puncture is the most valuable aid we have to fix the diagnosis beyond a doubt, because in the majority of cases tubercle bacilli can, by patient search, be found in the fluids.

In some cases tubercle bacilli are not found during life in the puncture fluid, but are found in very large numbers in the fluid withdrawn from the subarachnoid space after death. This can be explained by the fact that during life there is a constant circulation wave present in the subarachnoid space, which keeps the tubercle bacilli in equal suspension, thus few tubercle bacilli will naturally escape discovery. After death this circulation wave ceases, a sedimentation of the bacilli takes place, especially in the bottom of the spinal canal, and are thus easily withdrawn in the puncture fluid.

We have studied also the cytology of the fluid obtained by lumbar puncture in tuberculous meningitis. This cytology we have tabulated in 18 cases as follows:

CYTOLOGY OF THE FLUID OBTAINED BY LUMBAR PUNCTURE, 18 CASES OF TUBERCULOUS MENINGITIS

Per cent. Poly-nuclear cells.	Per cent. Mono-nuclear cells.	Per cent. Poly-nuclear cells.	Per cent. Mono-nuclear cells.

Fourteen cases examined for sugar 0 and albumin increased.

The cellular content of the fluid obtained by lumbar puncture in cases of tuberculous meningitis has been studied by Vidal, Sicard and Ravant and shown to be not only of great interest, but also of diagnostic import. Their studies have been enlarged by Lenhartz, Pfaunder, Councilman, Wentworth and others. It may be stated that in the fluid obtained from cases of tuberculous meningitis there is a predominance of the lymphocytes in the greatest number of cases. The rôle played by the polynuclear leucocytes has been a matter of much discussion and it has been shown that in rare cases the polynuclear leucocytes may predominate in the fluid obtained by the puncture. Bernheim, Moser and Marcon-Mutzner have published such cases. It may be said, however, that this polynuclear picture is not a primary one in tuberculous meningitis. It is found either in the latter stages of the disease when there is a great invasion of the tubercle bacilli into the diseased area or in cases in which there is a mixed secondary infection. At all events polynuclear is connected with an invasion of an increased number of tubercle bacilli or the breaking down of old caseous areas and thus numbers of bacilli are set free into the cerebro-spinal fluid so that an error which might be at first made by a misrepresentation of the predominance of polynuclear leucocyte is rectified by the increased number of tubercle bacilli in the puncture fluid. On the other hand lymphocyte is of the puncture fluid has been exceptionally in cases of meningism in typical cases of the serous meningitis of bronchopneumonia, of enteritis in the cerebral tumor and in the adult in syphilitic meningitis (Vidal). However, it is not

THE CONDITION OF THE EYES

Of great interest in this form of meningitis, as compared to other types of the disease, is the condition of the fundus. The eyes of all our cases of meningitis were examined by Dr Gruning or his assistants in the eye service of the hospital and he examined 46 of our cases of tuberculous meningitis. Of these cases the fundus was normal at the outset of 34 per cent of the cases. In 66 per cent of the cases there was some change in the disc, varying from optic neuritis to the presence of tubercle in the tissue of the choroid. In some cases the disc was simply swollen and indistinct in its margin, in other cases the veins were distended. The interesting fact is that choroid tubercle was present in 9 cases of the 46 examined as early as the second day of duration of the active symptoms of the disease, that is from the first to the sixth week of the disease. These tubercles in the choroid may be discovered at any period of the affection. I have seen them present in the fundus when the cerebral symptoms were insignificant.

As distinguished from this condition of the fundus in tuberculous meningitis, we may mention the fact that in meningitis of other types, especially in the cerebrospinal meningitis of the epidemic type, the fundus in the majority of the cases shows very little, if any, change throughout the disease. The presence of optic neuritis in cerebrospinal meningitis is exceptional; it certainly is not as frequent as in tuberculous meningitis.

PERCUSSION OF THE SKULL.

Of great value at the outset of tuberculous meningitis, where the symptoms are rather equivocal and while the child is still apparently conscious and plays during part of the day, is percussion of the skull. MacEwen was the first to apply this method of diagnosis, and his cases were mostly those of tumor or abscess at the base of the brain pressing on the veins in this locality and thus causing hydrocephalus. Although he investigated a large variety of cases in children and applied percussion of the skull to them in making a diagnosis of distension of the ventricles by fluid, he did not devote his attention to any one disease specially. In my studies of tuberculous meningitis and meningitis of the epidemic cerebrospinal type I have followed out percussion of the skull according to the method of MacEwen. This method I have described elsewhere, and I have applied it to healthy children in order to determine at what age this sign could be relied upon as an abnormal manifestation in children. That is, at what period of life the tympanic note obtained by percussion over the lateral ventricles could aid us in a diagnosis of hydrocephalus. It may be said that beyond the age of two to two and one-half years, when the skull is completely ossified, this sign should not be present if there is a normal conformity of the head and if there has been no pre-existing hydrocephalus.

In 34 of the 52 cases which I have studied of tuberculous meningitis I have found that a percussion of the head at a very early period of the disease following MacEwen's method as to the position of the patient, which should be upright with the head slightly inclined to one side, the percussion being performed at the pterion is a most valuable means of discovering the presence of hydrocephalus interna in tuberculous meningitis.

I recall the case of a girl of fourteen who had been ill only one week, complained of headache, felt tired, with a tendency to be drowsy at times of the day, at

others she was quite bright. The patient had absolutely no fever for eight days. When I saw the patient she was apparently asleep in bed, could be easily aroused, and when aroused recognized her physicians. There was very little rigidity of the neck, although Kernig's sign was present. Percussion of the skull cap in this case, according to the lines marked out by MacEwen, gave a tympanic note over the pterion, and on this I unhesitatingly made a diagnosis of hydrocephalus, to the astonishment of the physician, who thought he had to deal with a case of hysteria, knowing, as I did, that hysteria could certainly not produce a percussion note of tympanic character over the situation of the lateral ventricles of the brain.

This case was subsequently seen by other consultants, who were inclined at first to disagree with the diagnosis of tuberculous meningitis. A week subsequent to my examination the patient died with the classical symptoms of tuberculous meningitis, the other consultants agreeing in the diagnosis. Percussion of the skull at an early period of tuberculous meningitis is certainly one of the most valuable aids in diagnosis.

LUMBAR PUNCTURE

The fluid obtained by lumbar puncture in cases of meningitis of the tuberculous and other varieties has been studied as to the pressure under which it is contained in the ventricles and in the subarachnoid space (Quincke, Ricken, Falkenheim, Pfoundler). As to its appearance, speaking now of tuberculous meningitis, (Lichtheim, Schiff, Brenner), as to its density (Achord and Loeper), its cryoscopy (Widal and Sicard), its chemical properties (Gautier, Achard), its toxicity (Widal, Sicard, Lensé), and its agglutinating properties in case of the tubercle bacillus (Hawthorn).

All above directions of study are of great value scientifically and have their important remote bearings. Clinically, the physician at the bedside is not equipped to carry out methods which will give him details as to the above, and we must seek practical results rather from an examination of the bacterial and cellular content of the fluid obtained by lumbar puncture. Inoculations in animals and cultures are also tedious, and though certain as far as animal experiment is concerned, 100 per cent of the cases being positive (Widal and LeSourd), the physician seeking immediate results must resort to an examination of the centrifuged fluid by stain for the tubercle bacillus. Even here one would think that uniform results would be obtained. Marfan found bacilli only in exceptional cases, Heubner had similar results. Friedjung found them frequently, Kohts in 50 per cent of the cases, Pfaundler in 70 per cent of the cases, Schlavyk and Manicatide in 16 of 19 cases. Lichtheim found the tubercle bacillus always present. Pfaundler found the bacilli more readily in the later periods of the disease (75 per cent) than in the early stages (33 per cent). Our own cases seem to show that though in the later stages of the disease the bacilli may be more abundant, their presence in the early stages can be verified by patient search of the fluid.

I have intimated in this paper that in 52 cases of tuberculous meningitis I have been able to make a diagnosis clinically in the majority of cases without the aid of what may be considered our most valuable precise diagnostic method, that of lumbar puncture. In other words, lumbar puncture in the majority of my cases was performed after the diagnosis of tuberculous meningitis had been made as a possible condition. The

fluid withdrawn was then examined as to the presence or absence of tubercle bacilli

I have left this procedure for more detailed consideration because I wish to show that it is possible with moderate certainty, to make a diagnosis of tuberculous meningitis early in the disease from a consideration of clinical methods which I am describing. No case of tuberculous meningitis should be positively considered as such until it had been studied for some length of time, a few days at least, because first appearances are always deceptive, and such a diagnosis once made is quite a serious blow to the friends of the patient. We should be exceedingly cautious, therefore, not to fix the diagnosis of tuberculous meningitis without the aid of an extended previous study of the case either through another physician or our own study at the bedside. Once having made a diagnosis of its possible presence, we may then proceed, and then only, to make a lumbar puncture in order to fix the diagnosis beyond equivocation.

I have never made a lumbar puncture in these cases without feeling that a meningitis of some kind was present. In other words, lumbar puncture should be resorted to only as a means of confirming or excluding the presence of a disease whose prognosis is hopeless. In this respect is it valuable to the friends of the patient? It is in tuberculous meningitis, especially, that much confusion has resulted on account of the various data given in different clinics as the result of the careful examination of the fluid obtained by puncture. Personally we consider that lumbar puncture is an absolutely certain means in a majority of cases of confirming the diagnosis of tuberculous meningitis, for we feel that in the majority of the cases tubercle bacilli can be found in the puncture fluid if care and diligence be exercised. The fluid, of course, must be drawn so as to be free of the mixture of blood, and a certain amount of experience is necessary to succeed in this respect. It must then be carefully centrifuged in order to examine the sediment. During the past five years we have examined 66 successive cases, of which two were doubtful, diagnosed clinically as tuberculous meningitis with a view of detecting tubercle bacilli in the puncture fluid. In 42 cases we have found the tubercle bacilli. I may say here that one man alone examined all fluids, and it is due to his patience that we have been able to prove that a diagnosis is possible in the majority of cases from the examination of the puncture fluid. Dr. Bernstein of the Mt. Sinai Hospital staff has devoted his time to this study, and a more detailed account of this work can be found in a monograph recently published by him.

In previous years we have not been successful in obtaining positive results in the examination of the puncture fluid and we feel that this has been due to a faulty technique. In the years 1904 to 1906 29 cases diagnosed as tuberculous meningitis revealed tubercle bacilli in the fluid of puncture in 24. In two of these 29 cases a diagnosis was not fixed positively at the time of puncture. Thus in 24 of 27 cases punctured tubercle bacilli were found as confirming the clinical diagnosis. In those cases, it may be mentioned incidentally, in which tubercle bacilli were not found in the puncture fluid, the laboratory was kind enough to inject this fluid into guinea-pigs, and in this way secured a positive result. This, however, was in an early period of our studies on the disease.

Thus it may be said that, given a case which clinically

leads us to surmise the presence of tuberculous meningitis, a lumbar puncture is the most valuable aid we have to fix the diagnosis beyond a doubt, because in the majority of cases tubercle bacilli can, by patient search, be found in the fluids.

In some cases tubercle bacilli are not found during life in the puncture fluid, but are found in very large numbers in the fluid withdrawn from the subarachnoid space after death. This can be explained by the fact that during life there is a constant circulation wave present in the subarachnoid space, which keeps the tubercle bacilli in equal suspension, thus few tubercle bacilli will naturally escape discovery. After death this circulation wave ceases, a sedimentation of the bacilli takes place, especially in the bottom of the spinal canal, and are thus easily withdrawn in the puncture fluid.

We have studied also the cytology of the fluid obtained by lumbar puncture in tuberculous meningitis. This cytology we have tabulated in 18 cases as follows:

CYTOLOGY OF THE FLUID OBTAINED BY LUMBAR PUNCTURE IN CASES OF TUBERCULOUS MENINGITIS

Per cent. Poly-nuclear cells.	Per cent. Mono-nuclear cells.	Per cent. Poly-nuclear cells.	Per cent. Mono-nuclear cells.

Fourteen cases examined for sugar 0 and albumin increased.

The cellular content of the fluid obtained by lumbar puncture in cases of tuberculous meningitis has been studied by Vidal, Sicard and Ravant and shown to be not only of great interest, but also of diagnostic import. Their studies have been enlarged by Lenhartz, Pfaunder, Councilman, Wentworth and others. It may be stated that in the fluid obtained from cases of tuberculous meningitis there is a predominance of the lymphocytes in the greatest number of cases. The rôle played by the polynuclear leucocytes has been a matter of much discussion and it has been shown that in rare cases the polynuclear leucocytes may predominate in the fluid obtained by the puncture. Bernheim, Moser and Marcon-Mutzner have published such cases. It may be said, however, that this polynuclear picture is not a primary one in tuberculous meningitis. It is found either in the latter stages of the disease when there is a great invasion of the tubercle bacilli into the diseased area or in cases in which there is a mixed secondary infection. At all events polynucleosis coincides with an invasion of an increased number of tubercle bacilli or the breaking down of old caseous areas and thus numbers of bacilli are set free into the cerebral spinal fluid so that an error which might be at first made by a misrepresentation of the predominance of polynuclear leucocytes is rectified by the easy discovery of tubercle bacilli in the puncture fluid. On the other hand lymphocytosis of the puncture fluid has been seen exceptionally in cases of meningism in typhoid fever, in the serous meningitis of bronchopneumonia, in enteritis in the cerebral tumor and in the adjuvant syphilitic meningitis (Widal). However, it is a fact

may disappoint us as to the primary pathognomic significance of a lymphocytosis of the cephalorachidian fluid, we still can feel that in the presence of symptoms pointing clinically to a tuberculous meningitis a predominance of lymphocytes in the fluid obtained by lumbar puncture is of great value in coming to a definite conclusion as to the nature of the process in the meninges. It certainly rules out certain acute purulent forms of meningitis. Thus in our list of 19 cases 17 showed a predominance of lymphocytes to the extent of 70 per cent or more. In this we must not forget that in the so-called forms of basic meningitis (cerebrospinal acute) we may in the chronic stages obtain a lymphocytosis. In such cases, however, the history will aid us in coming to a conclusion as to the significance of the lymphocytosis. Thus it may be said that a polynuclear leucocytic predominance is certainly indicative of the acute suppurative forms of meningitis, the presence of an excess of lymphocytes in the puncture fluid to the extent shown is strongly in favor of a tuberculous process.

Of interest chemically are the facts that normally the cerebrospinal fluid contains a substance which reduces Fehling's, but does not rotate polarized light, this is absent in cases of tuberculous meningitis. There is also in tuberculous cases an increased amount of albumin in the cerebrospinal fluid, Arthus finds almost always a substance called serine. We will not dilate on this aspect of the question of composition of the cerebrospinal fluid, as it seems to have as yet a limited practical clinical bearing. Of 14 cases examined for me all contained an increased amount of albumin and in none was glucose present.

THE DIAGNOSIS

It will be seen from what has been said that the diagnosis of tuberculous meningitis in the early stages of the disease is feasible to-day, whereas it was well nigh impossible formerly. The slow onset interrupted by periods of irritability, etc., the irregularity of the pulse and respiration, the low or normal temperature, the absence of hyperesthesia, the lack of appetite, the discovery of hydrocephalus by percussion of the skull as described, will all lead us to establish a meningitis of the tuberculous type. If after this we can obtain by lumbar puncture an examination of the subarachnoid fluid, in the majority of cases, we will fix the diagnosis beyond a doubt. The examination of the fundus of the eye for changes which accompany tuberculous meningitis in the initial stage, although successful in a certain proportion, as has been shown in this paper, leaves us without any positive data in the majority of cases.

If we compare what has been said with what is known of the onset of several forms of meningitis, especially those of the cerebrospinal meningococcic or pneumococcic type, we will see that there can be no question, certainly in the vast majority of cases, as to the possibility of making a diagnosis. Aside from the examination of the puncture fluid, the onset in the acute forms of meningitis of the epidemic type is always abrupt and unmistakably so. The high temperature also in the acute cases of the suppurative type, the rigidity, the constant presence of a Kernig, and the active hyperesthesia will complete the picture.

More difficult, it seems to me, will be the diagnosis as to the specific form of meningitis in children below two years of age who have been sick for some length of time. In these cases we know that the posterior basic

forms of meningitis with their low or normal temperatures, the hydrocephalus, the low leucocyte count, the lack of hyperesthesia, the absence of anything even in the puncture fluid in some cases to aid us in a diagnosis, will make us fall back on the history of the case as to its acute onset before we can conclude whether we have a tuberculous process present or a chronic condition following an acute attack of cerebrospinal meningitis.

INTERMITTENT TICK FEVER

PRELIMINARY REPORT ON A NEW TYPE OF FEVER DUE TO TICK BITE (IXODIASIS) *

CHARLES F. KIEFFER, M.D.

Major and Surgeon United States Army

(On detached service with the Army of Cuban Pacification at Santiago de Cuba, Cuba.)

FORT D. A. RUSSELL, WYO.

The older physicians in the Rocky Mountain regions have always insisted that there is a special type of fever indigenous to this section of the country. This fever or, as it appears to me, groups of fevers, has been given various names, but principally that of mountain fever. The group has simply been dismissed in recent years, although many good observers still hold that there is a type of fever which is neither malaria nor typhoid. It has been very generally held that exact laboratory methods would place these supposed specific fevers as aberrant types of one or the other of the two diseases.

A beginning has been made, however, in the description of the "Spotted Fever of the Rocky Mountains." This affection is now generally conceded a specific nature. So far as known it is very closely limited to narrow tracts of country and has a dreadful mortality rate. It has been assumed, although on insufficient evidence, that the disease is a form of ixodiasis. It also seems likely that here there may be a question of more than one disease, since very dissimilar cases without eruption have been assumed to be mild forms of the more severe disease.

Careful laboratory investigations with the fevers at this post gave most unsatisfactory results. Time and again marked remittent and intermittent fevers were encountered and the blood examinations remained negative. As a result a discouraging number of entries accumulated on the sick report with the diagnosis "Fever, type undetermined." It was finally noticed that these fevers came in little groups. Then that the men affected had all recently returned from the vicinity of the maneuver reservation where they had gone either on fishing pass or on practice marches. Finally it was observed that all these men had been bitten by ticks and, indeed, a number of the men ascribed their fever to these tick bites. Working with these clues, much corroborative evidence was easily found. Then an opportunity arose to study six cases of fever arising in a party of eight men. These men had all been on pass in the mountains, and, of the eight, the six taken down with the fever had been bitten by ticks. Four of these six cases are here reported. Since that time the connection between the tick bites and the following fever has been frequently demonstrated. In July, 1906, there were under observation and study, in the post, three severe cases of tick fever developing in a party of five people who spent one night camping in the tick region. These cases are all identical with those to be described later.

* Special report to the Surgeon General U. S. Army published by his authority.

I believe that the connection between the tick bite and the fever is indubitable.

The region in which the men from this post have become infected is that section embraced in the headwaters of the three small streams which go to make up Crow Creek. A large portion of this territory is in the maneuver reservation.

From observations made here it appears necessary to produce the infection, whatever it is, that the tick should fasten itself on the skin of the patient. In other words, that the rostrum of the insect should become imbedded. It also seems likely that the number of ticks biting the patient has some influence on the severity of the following attack, although on this point I am not entirely clear. Certain it is that in one of the sharpest cases (Case 5) observed here the patient had the largest number of imbedded ticks. Twelve in all had fastened themselves into this man's skin. In all the cases not only was there an undoubted history of tick bites, but there was distinct evidence of the bite at the place where the insect had been attached. In many of the cases small nodules had formed at the point of attachment of the insect. These nodules persisted for weeks. They were hard, pale and quite painless and varied in size from that of a pea to a small marble. In other cases the location of the bite was marked by a small red papule. From a number of these papules the rostrum of the insect was recovered. In these the rostrum had evidently been torn off and left behind in improper attempts at removing the ticks. Beyond the conditions here described there was no local reaction to the bite of the tick. Particularly were there none of the sharp local reactions that are sometimes described, amounting in some cases to cellulitis or abscess formation.¹

A number of specimens of the tick were collected and sent to the office of the surgeon-general for identification on June 25, 1905. The ticks were referred to Dr. Charles Wardell Stiles of the Public Health and Marine-Hospital Service, who tentatively identified them as *Dermacentor andersoni*. This is the same tick which is supposed to be associated with spotted fever. Since that time I have had considerable correspondence with Dr. Stiles on the subject of the exact identification of this parasite with particular reference to its differentiation from *Dermacentor occidentalis* (Marx). He wrote me under date of March 5, 1906, that he has recently had an opportunity of examining all the original type specimens of *Dermacentor occidentalis* and finds that it is identical with *Dermacentor andersoni*. As the *Dermacentor occidentalis* has priority, the name *Andersoni* which he gave this special tick must be suppressed. The definite identification of the tick is, therefore, *Dermacentor occidentalis*.

GENERAL DESCRIPTION OF THE DISEASE.

Generally the cases correspond to one type. After a short period of incubation, with brief and ill-defined prodromal symptoms, the attack is ushered in by a chill. Beginning slightly before the chill there is nausea or vomiting and intense pain in the muscles and joints, increasing with the appearance of the chill and becoming more severe with the rise of temperature. The chill lasts two or three hours, and with it a febrile movement begins, lasting, as a rule, forty-eight hours although in exceptional instances it may only last twenty-four hours. Then a remission occurs and the tempera-

ture falls nearly or quite to the normal. The duration of the remission is about forty-eight hours, following which the same cycle is repeated.

As observed here the disease consists of from three to seven such paroxysms, after which the patient, barring a pronounced anemia, is well. There is another type, but not so common as that just described, in which after the initial chill the temperature rises, ladder-like, for two or three days. These cases have more marked prodromes and more marked abdominal symptoms (abdominal tenderness and enlargement of the spleen) and present a clinical picture which is, at first, extremely suggestive of typhoid fever.

PERIOD OF INCUBATION AND PRODROMAL STAGE

The period of incubation varies between three and seven days. In the majority of cases the initial paroxysm developed four days after being bitten by the ticks. In one case only was the period reduced to three days, and in one no symptoms developed for seven days.

Nearly all the patients went through an ill-defined prodromal period marked by languor, malaise, fleeting pains in the muscles and joints, headache more or less severe, nausea and vomiting. Following these symptoms the attack itself begins with the chill.

THE ATTACK

Initial Chill—The initial chill is present in all of the cases. It is severe and lasts from two to three hours. It is not an active chattering chill, like the cold stage of malarial ague, but is accompanied by much more discomfort and acute pain. Nausea and vomiting, even if not prominent during the prodromal period, now become marked. Following the chill there is a subjective sense of heat, although the actual rise of temperature begins with or shortly after the chill. After two or three hours there is a moderate sweating stage. With the beginning of the chill the headache and pains in the bones and joints become very severe. The patient is acutely miserable and suffers quite as much if not more than in the painful phases of dengue or epidemic influenza, certainly much more than in the ordinary benign malarial infections.

The Paroxysm—The fever rapidly rises to 103 or 104 F., and remains high with narrow fluctuations for forty-eight hours in the ordinary type of paroxysm. In some few cases the febrile stage only lasts twenty-four hours. After this stage is passed an intermission or remission occurs, during which the temperature falls to or near the normal. In this stage, as a rule, the patient is quite comfortable. The severe headache and bone and joint pains disappear. Nothing remains but a feeling of exhaustion and weariness. This intermission lasts forty-eight hours, thus completing the cycle, when a second chill takes place and the second paroxysm begins and terminates as the first, a two-day fever and a two-day intermission. The succeeding paroxysms after the second are apt to be progressively milder. Very exceptionally this rule of periodicity is altered and there is a one-day fever, but always then with a three-day intermission, in the large majority of cases however, the two-day fever and two-day intermission obtains.

Abdomen—Generally there is pain and some degree of tenderness distributed over the entire abdomen but nowhere very severe. In two cases there was a slight degree of meteorism with gurgling in the right iliac fossa. The tenderness is perhaps a little bit more pronounced over the hepatic and splenic areas. No enlargement of the liver could be certainly demonstrated.

¹ Vide Anderson's and Stiles' reports.

On the other hand, enlargement of the spleen with tenderness can be shown almost from the beginning, although moderate in extent. As has been already stated, a few cases presented rather more marked abdominal symptoms and, together with a creeping temperature, made at first a picture extremely suggestive of typhoid fever.

Urine—Nothing unusual was found in the urine of any of the patients. Numerous examinations showed some high specific gravities and the usual conditions found in febrile urines.

Blood—Particular attention was paid to the study of the blood and careful search was made for the so-called *Piroplasma hominis* (Wilson and Chowning, 1903) or some allied form. Some few objects were found resembling the published descriptions and drawings in Anderson's report.² A very careful study of these bodies leads me to the conclusion that they are either artefacts or, more likely, evidences of vacuolization of the erythrocyte with deposit of the staining materials in the margins of the vacuole. It seems to me that Craig's³ criticism of *Piroplasma hominis* is probably entirely correct. It impresses me that the evidence

Chart 1—Illustrating the temperature in Case 3

on which the validity of *Piroplasma hominis* rests is very insecure, and for that reason very little importance was placed on similar appearances in the blood of these cases.

There is a constant and progressive fall in the number of red cells. This fall was constantly observed and, paroxysm for paroxysm, is certainly as marked as the red corpuscle loss following severe malarial seizures. In some of these cases a numerical loss of almost 20 per cent followed one seizure. Particular attention is invited to the blood chart in Case 5, in which a daily complete blood study was made. In this case it will be observed that three two-day paroxysms resulted in a fall in the number of red cells from 5,800,000 (which is considered a fair normal in this altitude, 6,200 feet) to 2,600,000. The loss is apparent not only in the faces and mucous membranes of the patients, but also in the appearance of the blood drops taken for examination. The pallor and poverty of the blood is very apparent to the naked eye. The loss is replaced slowly and for two months in the patient whose chart is here shown there was well-marked anemia.

The hemoglobin loss follows the diminution of red

cells very closely. Therefore, the color index is not much disturbed. In this chart the hemoglobin fell to 48 per cent. (estimation with Dare hemoglobinometer). The restitution of the hemoglobin to normal is somewhat slower than the restitution of the red cells. Consequently during convalescence the color index is slightly minus.

With regard to the leucocytes no decided finding was made other than an increase in one type of cell. It is evident that there is no marked leucocytosis, although nearly all the cases showed a slight increase in their numbers. Differential counts showed a constant moderate increase in the large mononuclear cells which in numbers amounted not only to a relative but also to an absolute increase in their numbers. Six differential counts in Case 5 resulted as follows:

Polymorphonuclear	76.6	77	72	71	73	72
Large mononuclear	12.4	13.6	15.6	16.5	15.6	16.6
Lymphocytes	9.6	9	11	12	10	11
Eosinophiles	8	4	9	6	8	4
Mast cells	6	0	5	0	6	0
	100.0	100.0	100.0	100.0	100.0	100.0

This leucocyte formula is suggestive, since considerable stress has been laid on the significance of a marked increase in the large mononuclear cells in malaria. In the so-called human piroplasmosis (spotted fever of the Rocky Mountains) Anderson gives the following formula averaged from two counts in a case observed by

Chart 2.—Illustrating the temperature and remissions in Case 5

him, and it will be seen that the leucocyte change in this, too, is similar.

Polymorphonuclears	77.7
Large mononuclears	11.4
Small lymphocytes	10.0
Eosinophiles	9
	100.0

The agglutination reaction with the bacillus of typhoid fever was carefully and repeatedly looked for in each case, and in all the examinations were negative. Search for malarial parasites was also made in all the cases and in none were any found.

TREATMENT

Quinin was administered in all the earlier cases without any apparent effect. I believe that it increases the subjective discomfort. It certainly has no beneficial effect either on the paroxysm directly or in the line of preventing its recurrence. I am quite convinced that arsenic has a controlling and curative effect on the disease, particularly when used subcutaneously or intravenously. The subcutaneous injections are in my opinion, distinctly to be preferred to the intravenous but are apt to be followed by annoying burning which lasts from fifteen to thirty minutes. The best formula is Kobner's and if a little cocaine be added to it the burning will be prevented, thus

R Sodii Arsenitis 0.1
Cocain Hydrochlor 0.4
Aque 10.0

This solution should be sterilized and is used in a dose of from 1 to 2 cc twice daily. After the acute phases the blood deterioration must be met by smaller doses of arsenic or by the administration of the ordinary iron preparations.

Brief case histories of the six patients on sick report and of one case occurring in the post this year are here appended.

CASE 1—G B, private Eighth Battery Field Artillery, born in Michigan, 1870, in the service 20/12 years. Family history negative.

Previous Personal History—Diseases of childhood. Chan- croids one year ago.

Present Illness—He left post for the reservation on June 10, and returned on June 12. On the morning of June 12 he found five ticks attached. He had a severe chill on Friday, June 10, lasting about two hours, with severe headache and severe pain in all the bones and joints. He had fever all that day and the next, and then had two good days, during which he complained of feeling dragged out. He was admitted to sick report at the beginning of the second paroxysm, with a temperature of 102.3 F. Altogether he had six paroxysms of the two-day fever type with two-day intermissions. On the whole, this was a mild case.

CASE 2—F P P, private Eighth Battery Field Artillery, born in Kentucky, aged 24, in the service 210/12 years. Family history negative.

Chart 3—Blood chart in Case 5. The solid line shows number of red cells; the broken line shows hemoglobin percentage.

Previous Personal History—Operation for appendicitis three years ago, recovery complete.

Present Illness—He went to the reservation on June 10 and returned on June 12. During his stay there and after his return to the post he found six ticks attached. He had a severe chill on June 10, with fever, headache, and sore joints. The next chill was on Monday, June 19. It lasted three hours, with the same symptoms as before, with the addition of vomiting. The patient was admitted to hospital during the fourth paroxysm. On admission the places where he had been bitten were marked by hard, pale nodules the size of a pea. Five such nodules were found and one papule from which the rostrum of a tick was extracted. There was a marked anemia. The red cells numbered 3,050,000, hemoglobin, 60 per cent. This attack was apparently cut short by arsenic.

CASE 3—A M T, private Eighth Battery Field Artillery, born in Ohio, aged 25, in the service 7/12 years. Family and previous history negative.

Present Illness—He went to the reservation on June 10, returning on June 12. On June 11, Sunday, several ticks fastened on him, just how many he does not know. He had a severe chill with nausea, fever, headache and pain in the bones on Thursday, June 15. The chill lasted four hours and the fever all through the next day he says. The next chill was on Monday, June 19. He was admitted to hospital in his third paroxysm and had one more after entering, making four in all. On admission there were clear marks where four ticks had attached themselves to the skin. Chart 1 shows the last two attacks. The blood loss was moderate.

CASE 4—J S, private Eighth Battery Field Artillery, born

in Ohio, aged 23, in the service 9/12 years. Family and previous history negative.

Present Illness—He went to the reservation in company with the three other men on June 10, returning to the post on June 12. Some time on June 11 three ticks attached themselves to the skin. He had a chill with nausea and fever on June 14 and slight chilly sensations with fever on the fifteenth. The next two days he felt quite comfortable. Then he had another hard chill and thinks that the fever lasted three days with two days in between, when he felt tired out, but thinks he had no fever. On June 23 he had his third attack, for which he entered the hospital.

This was a mild case and complete recovery was fairly rapid. The blood loss was moderate.

CASE 5—C R, lance corporal, Hospital Corps, U S A. Family and previous history negative.

Present Illness—He went to the timber reservation on fishing pass on July 14. On the 15th several ticks bit him and the next day several more, in all twelve. He had a very severe chill on July 20 with nausea and vomiting. After the chill he had a severe fever and pains in the head and all the joints. The chilly sensations continued all that day and the following morning. The afternoon of July 21 he was admitted to hospital with a temperature of 104.2 F. He had then an active delirium. The second paroxysm occurred on July 24 and a third on July 28. After this third paroxysm the temperature remained continuously above the normal for several days and the usual remission did not occur until August 2. A mild at-

Chart 4—Illustrating temperature and remissions in Case 7.

tack was observed on August 4. Chart 2 shows the temperature changes in this case, and Chart 3 the blood changes. This man was acutely ill and in about ten days had developed a profound anemia, which is shown in Chart 3. For two months following the attack he was weak and pale and the blood recovery was slow and tedious. During the second week of his illness his disease represented what I have described before as the typhoid type with considerable abdominal tenderness, enlarged spleen and continuous though irregular temperature.

CASE 6—S E B, trumpeter, Company B, Eleventh Infantry. Family and previous history negative.

Present Illness—This man was in the party with the patient in Case 5. So far as he remembers six ticks fastened on him, although on admission to hospital only three papules could be found and one hard little nodule to show where the insect had taken hold. The initial chill came four days after, but was not severe. Three days later he had a second chill and on July 24 a third chill. All the attacks were accompanied by fever, headache and general aching and soreness. He was admitted to hospital in his third chill and he had a fourth and fifth paroxysm. He was not clear in his own mind as to how long the first three attacks had lasted. The first and fifth attacks, however, were of the one-day fever type with three-day intermission. This case was a mild one, but was complicated principally on account of the variation in the length of the attack. The length of time between the beginning of one attack to the beginning of the next was, for instance, the attack lasts but one day, but the fever continues three days. This phenomenon is very likely due to a delayed infection or to a decline in the virulence of the ticks at the end of the disease appearance.

CASE 7—Miss S., aged 24, white, female, unmarried. Personal history negative, has never had malaria or any other fever.

Present Illness—On June 14 she went with a fishing party to the dam in the reserve. On the 15th several ticks fastened on her. Three of these she pulled away forcibly and a fourth, she says, came off without any trouble. On the 18th she had a severe chill with nausea and vomiting. For several hours before the chill she had felt languid and had a slight nausea. She also had a slight headache. With the chill she had high fever and became delirious. The following day the fever had remitted about one degree (Chart 4) and the delirium had passed away, but she suffered very greatly from headache and pains all over her body. At this time two red papules were noticeable at a point near the right anterior superior spine of the ilium. From both of these the rostrums of the offending ticks were removed. There was another papule on the right chest and two between the shoulder blades. In one of these latter the rostrum of a tick was also imbedded. During the second day there was considerable tenderness over the entire abdomen, possibly a little more marked over the right iliac fossa, the liver and the spleen. The liver was not enlarged. The spleen was moderately enlarged and rather tender on deep pressure. On the third and fourth days the fever became almost normal, and the patient said that she felt well, although greatly weakened. The second paroxysm began on the fifth day, and the subjective symptoms were, if anything, more severe than in the first attack. From that time the course of the disease, as may be seen from Chart 4, was typical, the two day fever periods and two day intermissions continuing through six cycles. In this case there was considerable loss of weight, as well as a very severe anemia. The blood conditions in this instance have not yet been fully worked out.

IS SCARLET FEVER A STREPTOCOCCUS DISEASE?

LUDVIG HEKTOEN, M.D.
CHICAGO

Since the earliest application of microbiological methods to the study of scarlet fever the streptococcus has claimed the lion's share of attention. Its significance has grown as the observations have extended. At present the streptococcus is held by some to be the actual cause of the disease, while others, and I think the majority, look on it as essentially a secondary invader on which, however, depends to a large extent the fate of the patient.

For the purpose of discussing this question it is necessary first of all to consider the occurrence and the distribution of streptococci in scarlet fever. Numerous investigations¹ have indicated that streptococci occur on the tonsils of scarlet fever in far greater abundance than in health. In his study of the bacteria of the throat and skin in scarlet fever Weaver calls special attention to the enormous numbers of streptococci in the throat in this disease and to their gradual disappearance as convalescence progresses. For various reasons, but principally because of the lack of convenient means, most of the studies of tonsillar streptococci give few details in regard to the cultures obtained. On this account G. F. Ruediger² last year made a careful detailed study by means of the newer methods, of the streptococci and diplococci in the throat in scarlet fever, certain other diseases, and health. Ruediger made use of the blood-agar plate method of Schottmüller and Rosenow. On the blood-agar plate *Streptococcus pyogenes* produces

small gray colonies, surrounded by a perfectly clear area of laking, while the colonies of certain other chain-forming cocci and of pneumococci are green. His results must be considered as striking because they show that *Streptococcus pyogenes* is constantly present in great abundance on the tonsils of patients with scarlet fever and with simple tonsillitis before the throat symptoms begin to subside. He found *Streptococcus pyogenes* in small numbers only in 59 per cent of the 51 normal throats he examined, while pneumococci and the large groups of organisms (*Streptococcus viridans*) that lies between *Streptococcus pyogenes* and the pneumococcus were found in about equal numbers in the normal and the scarlatinal throats, thus showing that constant presence on the tonsils of *Streptococcus pyogenes* in large numbers is an outstanding feature of scarlet fever.

From the throat streptococci frequently pass to neighboring structures and give rise to more or less serious complications. They may also reach the circulating blood and cause streptococcemia as well as various internal and articular localizations.

In 100 unselected cases of scarlet fever in which I examined the blood systematically during life, streptococci developed in the cultures from cases, all of which recovered, although several were very ill.³ In Jochmann's series of 161 cases streptococci were recovered in 25 patients, all of whom died.⁴

By way of explanation of this divergence I may point out that my cases occurred in a mild epidemic, were strictly unselected, most of the patients being over 10 years of age and many over 20, whereas Jochmann's cases occurred in a frightfully severe epidemic, the patients being children under 10 and probably not strictly unselected. All observers agree that in fatal scarlatina general streptococcus infection is demonstrable after death in the large majority of the cases. Baginsky and Sommerfeld⁵ report streptococci in the blood and the internal organs of every one of 82 patients, including several in whom death occurred early and in whom there were no gross lesions. In other series general streptococcus infection was presented in a smaller percentage of the cases (Wright, Pearce, Slawek, Jochmann, etc.), and several instances of fatal fulminating scarlatina have been described in which there was no demonstrable evidence of serious streptococcus infection (Bohm, Jochmann). In general streptococcus infection *Streptococcus pyogenes* appears to be the predominating form, occasionally, however, we meet *Streptococcus viridans*.

Now, if streptococci play an essential and constant part in scarlet fever as, indeed, seems to be the case, then we would expect to find in the blood of the patients various specific antibodies of streptococci, more particularly agglutinins and opsonins. And in case the streptococci concerned in scarlet fever differ essentially from other streptococci we naturally would hope to find in these biologic reactions means of differentiating between them.

As a matter of fact, various observations have been made on the agglutination of streptococci by scarlatinal and other serums, but the results lack the desired uniformity. In an important article on the subject Weaver⁶ has pointed out that this in part may be due to technical difficulties and in part because it has not been recognized adequately that variations in the composition

and reaction of the culture medium have a marked influence on the agglutinability of streptococci

In general Weaver's results show that in scarlet fever agglutinins develop for streptococci, but that these agglutinins are not specific for streptococci obtained from cases of scarlet fever, and like agglutinins form to an equal degree in erysipelas and even in pneumonia and probably other infections not necessarily streptococcal. We see then that as the matter now stands no decisive conclusions are indicated by the agglutination of streptococci by scarlet fever serum as to their relation to scarlet fever. The scarlatinal streptococco-agglutinins should be studied still more closely in the hope of obtaining results of more positive significance. Thus, it is quite possible that fairly characteristic relations may be found to exist between the agglutinin curve and the course and character of the attack. Experiments with the serums of animals immunized with streptococci have given results that in some instances are rather suggestive of a degree of specificity on the part of scarlatinal streptococci. Ruediger found that most strains of *Streptococcus pyogenes* isolated from the throat in scarlet fever were clumped in fairly high dilutions of the serum of sheep immunized with an organism from the same source but not at all by the serum of sheep immunized with a streptococcus from phlegmon of the leg or with *Streptococcus viridans*. Here also further work is necessary.

As to the streptococco-opsonic index in scarlet fever I may say that a recent study in our laboratory by Miss Tunnichiff, the results of which are not yet published, indicate definitely that the index is below normal during the acute stages of the disease in the majority of cases, as the symptoms subside the index commonly rises above the normal to which the return may be more or less abrupt. During uncomplicated convalescence the index is normal or a little above. If complicating streptococcus localizations set in the index remains low until improvement begins. These variations in the streptococco-opsonic index appear to be specific because they are not associated with corresponding variations in the opsonic index for other bacteria such as the pneumococcus, the staphylococcus, and pseudodiphtheria bacilli.

From the facts presented in this condensed form we are justified in concluding (1) That the predominant feature of the bacteriology of the throat in scarlet fever is the constant presence of large numbers of *Streptococcus pyogenes*, (2) that the overwhelming majority of the so-called complications and of the deaths in scarlet fever are due to invasion of the tissues and the blood by this microbe, and (3) that in scarlet fever, even when mild, the organism gives evidence of systemic reaction to streptococci by variations in the streptococco-opsonic index and probably also by the formation of streptococco-agglutinins. There is, therefore, no escape from the conclusion that *Streptococcus pyogenes* or some form thereof plays a most significant part in the scarlatinal process, but are we ready to take the final step and to conclude that scarlet fever is wholly a streptococcus disease, all the phenomena of which, including the acquired immunity, are satisfactorily explained by the distribution of the cocci in the tissues and by the intoxication with their products?

It is quite true that many of the essential phenomena of scarlet fever, such as the initial symptoms the angina, the fever, the leucocytosis, and even the rash may be explained by what we already know of the pathogenic powers of *Streptococcus pyogenes* and which probably in

no small degree actually shares in their production, but there is no analogy in recognized streptococcus infections of the immunity conferred by scarlet fever even when mild. We have no evidence that scarlet fever leaves behind it any lasting immunity to streptococci, and we do know that the specific immunity which results from streptococcus infections in general is not at all marked and is only brief in duration. Consequently if scarlet fever is caused by a form of *Streptococcus pyogenes* this must be assumed to possess very pronounced and peculiar immunizing properties, of which as yet we have been unable to discover definite experimental or other evidence. There are other phases of this question that might be discussed with profit did space permit. For example, there is the reported lack of evidence of streptococcus invasion in certain instances of fulminating scarlatina.

Let us now for a moment consider acceptance of the streptococcal theory of scarlet fever from the point of view of the spread of the disease. This acceptance would seem to involve us in no special difficulty so far as the most important of the recognized modes of dissemination are concerned, namely, through contact in various ways

The Streptococco Opsonic Index in Scarlet Fever

with materials from the throat, it is different, however, with respect to the question of the infectiousness of the skin and the reputed longevity of the scarlatinal virus. It is universally believed that the scales of scarlet fever patients are infectious far into convalescence. According to Weaver's careful study, the bacteria obtainable in the skin and scales of scarlatina are quite the same as those found on the skin in health. Rackin obtained streptococci from the skin in 4 cases in 20, Gordon's search yielded no positive results, Weaver found streptococci in skin cultures in one case in 15, and Drever (unpublished observation) failed to find streptococci on the skin of 30 cases. The conclusion is plain—if streptococci cause scarlet fever they reach the surface of the body so rarely that the infectiousness of the skin must be greatly overrated. Medical literature contains numerous instances of apparent conservation of the scarlatinal virus over long periods of time—several years—whereas the longest time that Weaver could cultivate streptococci from preserved scarlatinal material was 90 days.

Thus it becomes evident that there are rather definite obstacles to the unreserved acceptance of the streptococcus theory of scarlet fever. The

specific cause of scarlet fever is not known⁷ and that the streptococcus is a concomitant or secondary invader for the growth and activity of which the conditions in this disease are peculiarly favorable, seems to me to harmonize better with the facts now at hand. This view receives strong support from the fact that smallpox when fatal is practically always associated with streptococcus invasion,⁸ so that the suggestion has been made that smallpox, too, is a streptococcus disease.⁹ Perkins and Pay¹⁰ dispose of this claim, however, by causing smallpox in the monkey with materials entirely free from streptococci, which by themselves, as expected, have no such effect.¹¹ It has been said that smallpox would be a relatively harmless disease were it not for the streptococcus invasion, and there are certainly good reasons to look on scarlet fever in the same light.

From the fact that there is no evidence in scarlet fever of increased activity on the part of pneumococci and certain related cocci that normally inhabit the throat, we may infer that the conditions in the scarlatinal throat are peculiarly favorable to *Streptococcus pyogenes*. Indeed, in view of the paramount importance of streptococci in the course and outcome of scarlet fever the chief significance of the pure scarlatinal virus would seem to lie in its power to open the door, so to speak, to streptococci. From this point of view the need for potent antistreptococcus remedies is as urgent and their eventual specific effects as logically explainable as would be the case were scarlet fever considered a streptococcus disease pure and simple.

One point remains. In view of the fact that streptococci grow in virulence in the susceptible animal organism it becomes our duty to guard carefully by adequate isolation against the transfer of especially virulent strains from patient to patient. We can understand from what we know of the dissemination of throat and mouth bacteria in coughing and other ways the great chance for such transfer when patients lie side by side in the same room. Perhaps the sad instances of several deaths from scarlet fever of children of the same family, sometimes spoken of as examples of family susceptibility to scarlatina, often result from the passage from child to child of especially virulent streptococci.

SOME SYPHILITIC DISEASES OF THE EYE

RANDOLPH BRUNSON, M.D.

HOT SPRINGS, ARK.

Of all diseases of the eye probably syphilis is responsible for a greater number of ocular affections than any one disease known, so I can not, in a paper of this character, go into an exhaustive study of diagnosis, prognosis and treatment, but will confine my remarks to giving the essentials of diagnosis, and take up each subject as seen from the anterior aspect of the eye.

⁷ Whether the protozoan like bodies described by Mallory (Jour. Med. Research 1904 x 483), in the skin of scarlet fever the parasitic nature of which is corroborated by Duval (Virchows Archiv 1905 170 485) but questioned by Field (Jour. Exp. Med. 1905 xli 343) have any etiologic significance is of course a question for the future.

⁸ Ewing Trans. Assoc. Am. Phys. 1902 xviii, 208.

¹⁰ Jour. Med. Research 1903 x, 105.

¹¹ On account of incommunicability of scarlet fever to animals the investigator is without ready means to determine whether scarlatinal materials or microbes he may isolate therefrom have specific pathogenic powers.

EYELIDS

Secondary syphilitic ulcers may occur in the eyelids from the breaking down of a gumma originating in the skin or in the subcutaneous tissue and cartilage. The most frequent location of the lesion is in the skin, near the lid margin or below the inner canthus, though it may occur on the conjunctival surface of the lid. It manifests itself usually at a late stage of the disease and should be classified as a tertiary lesion. The fact that this lesion may occur after all other symptoms of syphilis have subsided necessarily makes a diagnosis rather difficult, especially if it is situated over the lachrymal sac, in this event dacryocystitis is apt to be confounded with it. It is at times difficult to differentiate between this lesion and epithelioma, as the latter occurs more frequently on the eyelids than elsewhere.

CONJUNCTIVA.

The conjunctiva is very rarely affected primarily, but inflammation usually occurs when the iris and ciliary body are involved, the edema seen in these cases being caused by an obstruction to the return flow of the circulation. It has been my good fortune to see one case of gumma of the conjunctiva, this in a man 36 years old, who had been infected six years previously. The patient had received treatment for about three months after the initial lesion, and in the following year also he had taken more or less treatment, but, as all symptoms of syphilis had long since disappeared, he did not appreciate the necessity of further treatment, and the gumma of the conjunctiva was a result four years later. When I first saw him there was a round, hard mass, the size of a pea, glazed in appearance and almost white, situated at the sclerocorneal junction on the outer side of the right eye. Though he gave me a history of syphilis, a diagnosis was not made at the time, as I was uncertain as to the character of the trouble, and I requested him to return later in the week. On his return he told me that he had spent a very uncomfortable night with his eye. Examination disclosed a true broken-down gumma, ulcerated, and the whole surrounding tissue deeply injected. A salve of iodoform was prescribed to be used locally, and subcutaneous injections of the albuminate of mercury were begun at once, with iodid of sodium internally. After twelve injections, one given daily, and taking iodid up to 225 minims per day, the gumma completely disappeared, except for a slight contraction of the tissue.

For the past five years I have made a practice of examining the conjunctiva of each syphilitic coming into my office, my object in doing this was to find a mucous patch, but so far my efforts have been in vain. However, I expect some day to find one, as there does not seem to be any reason why they should not be found on the conjunctiva as they are elsewhere.

LACHRYMAL SAC AND DUCT

The lachrymal sac and duct is frequently invaded by syphilis through the nose. In all the cases of stricture of the lachrymal canal in syphilis which have come under my observation I have always been able to find the cause in the nose. Syphilitic rhinitis, both acute and chronic, is very common, and when we have great destruction of the nasal bones and membranes dacryocystitis usually occurs with varying severity.

THE CORNEA.

Interstitial keratitis has its origin in syphilis in perhaps 60 per cent. or more of all cases, and the true form

SYPHILIS OF EYE—BRUNSON

1161

is always hereditary. I have never seen a case caused by acquired syphilis, and believe the cases reported as such have simply been produced by iridochoroiditis, which has involved the deep layer of the cornea. Antonelli directs attention to the ophthalmoscopic appearance in congenital syphilis, namely "A certain degree of pallor, sclerolary border, a certain narrowing of the retinal arteries and a granular state of the retinal pigment." The symptoms of this variety of keratitis are a grayish discoloration at the periphery or some other part of the cornea. This color soon spreads over the whole of the membrane, which is infiltrated and its surface dull. At first the infiltration is translucent, it then becomes thickened and of a grayish tint, becoming darker until the iris is quite obscured. There is ciliary injection without congestion of the conjunctiva, lachrymation, photophobia and ciliary pain are also present, the latter due to an iritis which is nearly always present in these cases. The deep punctate keratitis of syphilis is situated in the deeper planes of the cornea, the iris, ciliary body and choroid are nearly always invaded. We have numerous small, deep infiltrations appearing in front of Descemet's membrane and in the center of the cornea. These infiltrations may become ulcerated in a few cases and leave very dense and permanent opacities. A word in regard to the treatment of these forms of keratitis. I have never seen a case, no matter how ill nourished and cachectic the patient may have been, that small doses of mercury did not act in a most satisfactory manner from the very start. It seems to exert a tonic influence.

IRIS AND CILIARY BODY

The iris and ciliary body are perhaps more often invaded by syphilis than any other part of the globe, and syphilis is the common predisposing cause of iritis. About 70 per cent of all cases of iritis are caused by this disease, and I have found in examining the histories of 1,500 cases of syphilis, reported in a previous paper,¹ that iritis occurred in over 3 per cent of all cases. There are a certain number of cases in which the clinical aspect will not give any indication of the constitutional cause of the inflammation, so we are more or less dependent on the history of the case and other data to confirm our diagnosis. In syphilis there are a certain number of characteristic signs in a given number of cases which will allow us at once to recognize the etiology of the disease. The most palpable of these are the papules—small raised masses imbedded in the iris, usually not exceeding three in number and generally located in the pupillary zone, but they may be seen at the periphery of the anterior chamber, or elsewhere. They begin as small points, increasing in size, until finally, in a few cases, they may attain such size as to touch the posterior surface of the cornea. During this time their color changes from a reddish brown to a lighter shade, and on closer inspection we shall find numerous small vessels surrounding them. They may disappear completely, or leave small arch-shaped synechiae. A white line is not infrequently seen at the bottom of the anterior chamber, due to the accumulated debris of broken down condylomata. At the pupillary edge of the iris, a rusty hue is sometimes observed, and is probably due to condylomatous masses, diffused throughout the tissues in that position. The posterior synechiae in this form of iritis are suggestive of the etiology of the trouble, as they are

broad and dark in color, thus differing in a marked degree from those of rheumatism, for instance, which are thin and light in color. This then, is the iritis of secondary syphilis, which is nearly always of a plastic type and has little tendency to recur. In nearly all cases attachment between the iris and the lens capsule takes place, unless the case is seen early.

Hereditary syphilitic iritis appears in the first few years of life, and also at a much later period. According to Hutchinson, the average age at which infantile iritis begins is five months, it affects females more often than males, attacks one or both eyes, and, though generally associated with a free exudation of lymph is not much marked by redness of the eye. The cornea remains clear and the ailment is attended by few of the more severe symptoms met with in adults. Most of the cases show one or more of the signs of hereditary taint—as cachexia, psoriasis-like cutaneous eruptions, aphthae or sores about the mouth, condylomata about the anus, or "snuffles." When iritis attacks other subjects it may occur alone or with interstitial keratitis. If alone, the inflammation usually appears in the ciliary body, and spreads to the iris at a later stage, so we have an irido-cyclitis. It is very hard at times to recognize as patients in other cases we may find associated with it, disseminated choroiditis, which is characteristic of syphilis. The iris reacts to light very sluggishly and ciliary congestion, purplish in color and patchy in distribution, is present. Sometimes a pupil may get blocked by a grayish layer of debris which seems to cling to the edge of the iris, and punctate deposits constantly appear in the cornea. Secondary glaucoma is a frequent sequel. In hereditary syphilis, iritis assumes the form of a serous irido-cyclitis and may appear alone or with interstitial keratitis.

Syphilitic cyclitis may be plastic, serous or gummatous, and is almost invariably associated with iritis, the symptoms are pain diminished vision due to deposits upon the posterior surface of the cornea precipitates in the vitreous, exudations between the iris and lens capsule, and ciliary injection. Galewski, in studying symptoms of syphilis in the ciliary body says

1 Whenever syphilitic iritis is accompanied by punctate keratitis either chronic or recent, areas of atrophic choroiditis will be found in the ora serrata.

2 In parenchymatous interstitial keratitis when due to hereditary syphilis disseminated plaques which sometimes reach the posterior segment are seen in the ora serrata, more often, however they are confined to the ciliary region.

3 Diffuse syphilitic choroiditis with disease of the vitreous always presents atrophic alterations of the ora serrata and the opacities of that humor are due to the latter lesion.

4 In ataxic atrophy of the discs atrophic and pigment changes occur in the ora serrata.

5 In syphilitic inflammation of the cerebral or cerebra spinal nerves characteristic signs of the disease appear in the ora serrata.

Gallenga reports two cases of syphilitic gumma of the ciliary body, but I have never seen a case. Before leaving the subject of irido-cyclitis I wish to make a few remarks upon the pathogenesis of primary iritis of syphilis. Brailey says

Almost all ailments capable of giving rise to inflammation of the iris are intimately associated with, if not actually caused by micro-organisms. As regards syphilis gonorrhoea tularemia leprosy influenza and relapsing fever this fact will be admitted by none. Organisms have been isolated in the fevers—typhoid smallpox and pneumonia—during recovery from which inflammatory infections of the iris and ciliary body may occur. From all the facts?

¹ Relative frequency of Iritis in Syphilis and Rheumatism observed in 3 000 cases. Ophthalmic Record, November 1899

subject, it would indicate that syphilitic iritis is due to the presence of microbes

Alexander believes that specific iritis is produced by vascular alterations, and points to the fact that Fuchs and Friedal have shown that the walls of the vessels of the iris are the seat of a gummatous degeneration. Brailey states that the ordinary form of the disease appears as an early secondary symptom during the time when the specific virus is diffusing itself, by means of the blood, throughout the entire economy. Nodular growths or condylomata are present in every case and are strongly suggestive of local irritation, such as might well be set up by bacilli deposited from the aqueous humor. Bronner has given particulars of three cases in which concussion of the eyeball was followed speedily by local syphilitic disease.

In many cases of irido-cyclitis, the patient tells us that the disease was set up by some slight injury to the eyes. A case in question came under my care some months ago.

History ———, aged 38 years, was walking along the street, carnival week, and a woman threw "confetti" into his face, some of which got into his left eye, producing at the time more or less irritation. Two days later, he came into my office with a typical case of specific irido cyclitis. A history of syphilis was obtained, but he had never had iritis before, so it would seem that the bacilli deposited by the aqueous humor were there and only required some slight irritation to start them working industriously.

RETINA.

That syphilitic retinitis, pure and simple, does exist, seems to be beyond question, as such careful and painstaking observers at Lebreich, Mooren, Mauthner have reported cases, while Ole Bull reports its occurrence in half of all the syphilitic cases seen by him.

We have observed in cases of severe iritis, more or less irritation of the retina. During the past twelve years I have had exceptional opportunities for observing syphilitic diseases of the eye, and in this time I have seen at least three positive cases of syphilitic retinitis without the choroid or iris being involved. The three cases were all due to the acquired form of syphilis, and appeared from four months to seven months after infection. In one case the retinitis was preceded by iritis, but the latter trouble had entirely subsided without injury to the eye. The most remarkable incident, outside the rarity of such cases, was that none of these patients had been fully under the influence of mercury, though each had been using inunctions for several weeks previous to the discovery of retinitis. I will not go into the details of these three cases here, as I expect soon to make a further and more elaborate report. In two cases there were dust-like particles in the posterior part of the vitreous, producing a cloudy appearance in front of the papilla. In the other case this condition was absent. In all there was a grayish opacity of the retina, and particularly along the course of the blood vessels, small, white foci were seen towards the periphery of the retina, developing along the course of the blood vessels, berry-like in appearance and covering the vessels in places. The arteries seemed somewhat thinner, and the veins were much larger than normal.

Syphilitic hemorrhagic retinitis not infrequently occurs in the course of syphilis and usually in the tertiary period of the disease. Of course, the predominating clinical symptom is a great number of hemorrhagic spots of different sizes and shapes, dust-like opacities are seen in the vitreous, the retina appears opaque, the

arteries are small and the veins are dark and large. Persistent headache is a constant factor in this disease until the patient is thoroughly under the influence of mercury and iodids.

Relapsing syphilitic central retinitis is a very rare affection, personally, I have seen only 1 case in about 2,000 cases of syphilis which have been under my observation. There is a sudden disturbance of vision, which disappears after a few days, to reappear. These recurrent attacks may keep up indefinitely. During the attacks the vision is much impaired. At first the vision is very good between the attacks, but later it is reduced. There is seen a slight shadow on the macula, but the papilla and surrounding field remain perfectly clear. Fine white points appear in groups around a grayish macula and during the intervals of attacks this cloudiness disappears entirely. In my case the trouble was cured after three months of heroic anti-syphilitic treatment. Three years have passed since the case was first seen and there has not been any recurrent attack.

Transitory recurrent bitemporal hemianopsia may be caused by syphilitic tumors affecting the chiasm. Oppenheimer regards this form of hemianopsia as a sign of basal syphilitic lesion.

Swanzy directs attention to the fact, that symptoms caused by syphilitic gummata at the base of the brain are frequently inconstant, that is to say, a nerve which is paralyzed to-day, may be found to perform its functions well to-morrow, while the paralysis of some other nerve may continue. In nearly all cases of hemianopsia and blindness brought about by gumma situated somewhere in the optic tract and chiasm, if the blindness is recent, we can, with a great degree of certainty, hope for useful vision, if not for entire relief. This, of course, can only be brought about through heroic anti-syphilitic treatment. Diseases of the blood vessels of the retina and iris caused by syphilis, while not very common, yet occur with sufficient frequency to attract attention.

Syphilis not only induces inflammatory changes in the retina as elsewhere, but frequently produces changes in the blood vessels similar to those seen in senile or albuminuric sclerosis. Blood extravasations, opacities of the vessels and sometimes retinal opacities are seen.

In syphilis, Haab attaches considerable importance as a diagnostic sign to decrease of the retinal vessels when the opacities of the walls appear as fine disseminated scales upon the arteries. He states further that other similar vessel-degenerations rarely show this appearance. New vessel formation is quite frequent in syphilis and takes place after hemorrhages of syphilitic origin.

CHOROID

Disseminated choroiditis is caused by syphilis in perhaps 80 per cent of all cases. In acquired syphilis the disease makes its appearance in from six to eighteen months or possibly longer, after infection. In hereditary syphilis the disease comes on in the first three or four years of life, or probably at a later date. In the early stages, in the acquired form, we see perfectly round white spots of a pinkish hue. The retinal vessels are clearly seen as they pass over the spots. The next change takes place in the center of the spot which becomes very white, at the same time the pigment ring begins to show itself and gradually becomes darker. The pigment ring and other details now sharpen up and the enclosed surface appears as a dull, yellowish-white plaque. Sometimes little shreds of lymph are seen during this stage attached by one edge to the choroidal plaque and undu-

lating in the vitreous. Patches of complete atrophy appear, bounded by a ring of black pigment, the entire surface in this ring is white or bluish-white and glistening, and we cannot see any trace of the choroidal vessels or pigment, yet the retinal vessels go across without interruption. The appearance of the fundus, between the choroidal spots, is usually normal. When the inner layers of the retina become affected the case is always more or less sericus and a loss of sight may take place either from atrophy of the disc or from detachment of the retina.

Iritis, interstitial keratitis and scleritis may make their appearance during the course of the disease. Liquefaction of the vitreous may take place with partial or complete dislocation of the lens. The occurrence of a group of yellowish-white flecks near the macula and of dust-like opacities of the vitreous, with change in the walls of the choroidal and retinal vessels, is nearly always characteristic of syphilis.

Syphilitic chorio-retinitis is always characterized at first by fine dust-like vitreous opacities and increased redness of the disc, which latter is surrounded by a halo of grayish discoloration. There is an absence of the patchy condition characteristic of choroidal inflammation alone. This form is frequently preceded by iritis. Night blindness is usually a marked feature. The field of vision rarely shows any marked diminution. In the early stages the diagnosis is quite difficult, there is a smoky appearance of the details of the fundus, however, which is characteristic. The vitreous opacities, increased redness of the disc and opacities of the surrounding retina, are frequently the only diagnostic signs.

Later, as the disease progresses, there is often found overfullness of the retinal veins with a contraction of the calibers of the arteries and paleness of the disc.

POLYCYTHEMIA.

J. F. ALDRICH, M.D. AND LE ROY CRUMMER, M.D.
SHEWANDOAH, IOWA. OMAHA.

The recent exhaustive articles¹ on this subject have changed our plans in considering the condition in detail and referring to the previous work which has been done on this subject, but cases are still so rare that we think it expedient to report this one in considerable detail. This case seems of especial interest in that while it has the entire triad of symptoms completely developed, it differs in some important essentials from the cases previously reported.

Patient—Mrs. J. M. D., aged 53, first seen by Dr. Aldrich Jan. 11, 1906, complained of considerable dyspnea on exertion. She had also noticed that she had an immense growth in the left abdomen.

Family History—This was negative. The father was living at the age of 88, and was in reasonably good health. The mother died at 50, from a "lingering consumption." The patient had waited on her mother constantly for three months prior to her death, but developed no symptoms following this exposure. She has two brothers living, aged 50 and 55 years respectively, and both in good health. Four sisters died in early infancy, the causes of their deaths being unknown to the patient. One brother died of a wound received in the Civil War when but 20 years old.

Personal History—When a child the patient had eczema on the scalp and along the shins, and at about the same time, had a severe attack of ringworm. She also had measles, scarlet fever, chickenpox and mumps during childhood. She never had any of the other diseases nor has she ever been seriously sick

at any time since puberty. There was no history of typhoid or malaria, and she has never had symptoms which would indicate a tuberculous infection. Menstruation began at 14 and terminated in a normal climacteric at the age of 50. Before marriage she had dysmenorrhea but was much better after marriage, and has considered herself normal in that respect ever since. She has borne six children, the latest eleven years ago.

History of Present Condition—For eight years she noticed a redness of the face so striking at times that even the school children noticed it and would run past her house exclaiming: "Look out for the red Indian woman." During this entire period she had a feeling of fullness of the head and dizziness at times. This still continues, but occurs only at comparatively long intervals. Three years ago she first noticed a tumor in the abdomen, which enlarged rapidly, and at the end of the first year was as large as a coconut. This tumor grew slowly, but continuously, and she did not notice at any time a decrease in size. She never had any form of hemorrhage.

Symptoms—The patient complained of extreme fatigue, a feeling of weight and dragging in the abdomen, and pressure over the bladder. She suffered somewhat from nausea, a slight distress after eating, and occasional attacks of diarrhea. She never had fever but perspired easily. There had never been much loss of weight.

Present Condition—Jan. 11, 1906. Patient was in fair flesh, had no difficulty in walking, and showed no trace of fatigue after rather a hard trip. The color of the face and hands was striking. The exposed skin had a dusky red color, and on closer examination, enlarged veins were seen in fine network throughout the skin. The conjunctiva presented the same appearance. The teeth and gums were normal. There was no tonsillar enlargement. The cervical glands, as well as those in other regions, were normal. The lungs were normal save for a slight emphysema. The heart was normal in size and sounds, and there was no dulness of the mediastinum. Examination of the abdomen showed no ascites, no enlarged veins, and the liver not perceptibly enlarged. The entire left half of the abdomen was filled with a heavy tumor, which came out from under the costal border at the seventh cartilage, extending down to one inch to the right of the umbilicus. One inch below the umbilicus it turned and ran almost horizontally across to the antero superior spine of the ilium, and thence behind the crest of the ilium. There were three typical notches of the median edge, which however, were very blunt. Careful palpation gave an impression that this tumor was thicker in the anteroposterior diameter than is usual with splenic enlargements. The length of the anteroposterior diameter from the costal border to the lowest point in the abdomen was seven and one half inches. The tumor was seven inches from the extreme right edge to the point where it disappeared behind the crest of the ilium. The skin was everywhere mottled but there were no enlarged veins except on the face and hands. There was no edema, but some tenderness on percussion over the sternum, tibia and other long bones. Urinary examination gave normal findings.

Blood Examination (Crummer) —

Red blood cells (Thoma Zetka)	7,700,000
White blood cells	4,700
Hemoglobin (F. M.)	1.0 per cent
Index	approx. 4.5

Smears stained by the Ehrlich's nitrophile and eosin methylene blue method showed considerable variation in the size and contour of the red blood cells. There were many microcytes and a few pale staining macrocytes. A few cells show slight poikilocytosis and in almost every field polychromatosis could be recognized. Nucleated red cells were found in considerable numbers. While counting 200 white cells 24 nucleated red blood cells were seen, which equals 600 nucleated red blood cells per c.c.m. Five or six were typical normoblasts while the others showed many characteristics of the megaloblastic type of cell.

The differential white cell count showed

Polymorphonuclears	72 per cent
Eosinophiles	4.9 per cent
Large lymphocytes	4 per cent
Small lymphocytes	11.9 per cent
Mycocytes	4.5 per cent

¹ Englebach and Brown. THE JOUR. A. M. A., Oct. 20 1906.
This article contains a complete biography.

Treatment—Acting on the advice of Turk, the patient was placed on Fowler's solution, which, however, she did not stand very well, and a pill, containing arsenous oxid, 001 gm, pepper, 020 gm, and licorice, 050 gm, was substituted with the same bad results. The tumor mass was regularly given fifteen minutes' exposure to the Roentgen ray, and an abdominal support was ordered.

Subsequent History—On February 11, the patient again presented herself for examination, feeling much better, and stronger in every way, the symptoms had practically disappeared. She had had eleven Roentgen ray treatments. The tumor was smaller in size, its transverse diameter being four and one-half inches, while its longitudinal diameter was five and one-half inches. The anteroposterior diameter had diminished, and it had assumed more nearly the shape of the ordinary splenic tumor. On examination the urine was found normal in every particular. The blood pressure by the Riva Rocco (wide cuff) apparatus was 132 mm.

Blood examination on this date

Red blood cells	6 048 000
White blood cells	5 500
Hemoglobin	90 per cent.
Index	approx 3/4

The microscopic findings were the same as at previous examination.

Jan 5 1907. It has been impossible to make further blood examination of the patient, but a report was just received stating that the patient continued well during the spring and summer, was able to work, and was entirely relieved of pain and distress in the abdomen. She had an attack of jaundice during August and the early part of September, which gradually cleared up, and since that time she has been less cyanotic. In September the spleen began to enlarge again, but on taking Fowler's solution it gradually diminished in size and is now less than half as large as it was at the time of first observation. Now it does not extend to the median line or as low as the umbilicus. Subjectively, she feels better and stronger in every way.

This case presents the usual features of polycythemia in its characteristic form, as in cases hitherto reported. It is furthermore one of the few reported cases in which improvement has been definitely noted. Concerning the theories of pathogenesis applied to this case, we have, it is true, a history of exposure to tuberculosis before the disease began, which might support the theory of Rendu and Vidal,² as to the tuberculous origin of this trouble, but careful examination showed absolutely no other signs of a tuberculous process, and it would hardly be fair to assume that this case was also one of localized splenic tuberculosis, particularly as the blood examination showed more definitely than in any of the hitherto published cases, the signs of an irritative lesion of the bone marrow (megaloblasts and myelocytes) thus in a great measure substantiating Turk's³ assumption that polycythemia is in reality a primary disease of the red bone marrow.

Removal of Foreign Bodies from Female Rectum.—Kakuschkin states in the *Russische med. Rundschau* for December that it is an easy matter to remove a foreign body from the female rectum if it is manipulated downward with two fingers of the hand introduced into the vagina. The perineum is pressed up and back by the other hand at the same time. In a personal case the nozzle of a syringe had dropped off in the rectum and the passage of stools failed to dislodge it, but it was readily manipulated downward with two fingers in the vagina. He remarks that the lower segment of the rectum belongs to the gynecologists, and that unless a foreign body is soon removed it is liable to be forced upward with the antiperistaltic movements.

THE RADICAL MASTOID OPERATION *

FRANK ALLPORT, M.D.

Professor of Otology and Clinical Professor of Ophthalmology and Otology, Northwestern University Medical School, etc.
CHICAGO

(Concluded from page 1092)

Ballance, of London, makes a plastic operation that is used by many operators and undoubtedly yields good results. He cuts through the inferior wall of the cartilaginous meatus (Fig 27) from its tympanic end to the inferior portion of the concha. This incision is then curved (Fig 28) upward and backward until the level of the anterior beginning of the helix is reached where it stops.

This cartilaginous flap is thinned of all possible superfluous tissue, and sometimes of some of its cartilage, and is then turned back and the curved portion fastened with through and through sutures (Fig 29) to the large anterior mastoid flap (Fig 30). The parts are thus placed in position (Fig 31) and the meatus expanded and forced against the bone as well as possible by firm gauze packing (Fig 32). Some operators do not trust to the various flap operations to epidermize the bone cavity, and claim surer and speedier results by grafting skin into the cavity, either at the time of primary operation or at a secondary operation performed in from ten to fourteen days after the original procedure, by first completely reopening the wound, then grafting and again closing the wound, as recommended by Ballance. I do not use grafts at all unless in the subsequent healing of the case they become indicated, which I find to be rather seldom, nevertheless, there is no good reason for not using them and they undoubtedly expedite and assure perfect healing. Such skin grafts may be very large as recommended by Ballance (Figs 36, 37, 38), who usually finds one graft to be sufficient, or smaller as proposed by Jansen and others, but of whatever dimensions they may be used they should, of course, always be cut as thin as possible by a sharp flat razor, the blade being lubricated by a warm normal salt solution. The graft may be transferred from the razor to a warm wet spatula (Fig 34) by means of needles (Fig 33) with handles, and then placed in its position on the bone by the same instruments, being, of course, careful to wipe the parts as dry as possible before the graft is permanently placed. It may be coaxed into its position by firmly twisted cotton on an applicator or by the "stoppers" (Fig 35) as devised by Ballance. The grafts may be held in position by small balls of cotton dusted with aristol or xeroform powder, or Ballance recommends that the entire operative area be covered first with gold foil and then packed with small antiseptically-dusted cotton balls or with narrow, dry gauze (Fig 39) and allowed to remain for one week and then removed by the meatus, as, of course, the post-auricular wound is immediately closed after the placing of the grafts, packings, etc. Some operators graft by placing either large or small pieces of tissue on the raw surfaces, through the meatus, and holding them there by small pledgets of gauze or cotton. This procedure is performed at varying times after the major operation, some preferring to do it at the first dressing, others a little later, and some only grafting at all when obstinate, unhealed surfaces call for such a procedure.

* Figures 42, 43, 44 and 45 are omitted. They will appear in the reprints of this article.

AFTER TREATMENT

Leaving the subject of skin grafting now and taking up the after treatment of cases on which radical mastoid operation has been performed, it may be said that the bandage should remain in position, unless contraindications occur, for three, four or five days, when it should be carefully removed with an abundance of irrigation to avoid pain and injury. The area operated on should be thoroughly irrigated, cleaned, soaked with some antiseptic solution, dried, dusted with xeroform powder and firmly repacked with gauze and then bandaged. I be-

lieve many excellent operations are spoiled by poor after treatment, and by this I refer especially to poor packings, as exuberant granulations are the menace of good healing. These cavities should be kept tightly packed until dermatization is well under way. It should be remembered that in this large, surgically produced cavity are several sub-cavities of varying sizes and depths. In the first place there is the large antrum and mastoid cavity, that should be kept firmly packed to its utmost recesses. This cavity being back of the meatus, and, therefore, somewhat out of sight, is apt to be neglected by the dressing surgeon, in which case exuberant granulations will speedily form and unpleasant and embarrassing complications will surely occur. Then there is what is left of the osseous meatus, with the inner tympanic wall at its extremity. This must be kept firmly packed as granulations will spring up and occlude the meatal space, thus hindering and sometimes nullifying the results of a good operation. There is also a somewhat curving, gutter-like concavity, representing the aditus ad antrum, connecting the tympanic and antral cavities, in which exuberant granulations are likely to form, with their embarrassing consequences where great pains should be taken in the packing (Fig 40).

Fig 27—The Ballance flap (After Ballance)

It should be remembered that in this large, surgically produced cavity are several sub-cavities of varying sizes and depths. In the first place there is the large antrum and mastoid cavity, that should be kept firmly packed to its utmost recesses. This cavity being back of the meatus, and, therefore, somewhat out of sight, is apt to be neglected by the dressing surgeon, in which case exuberant granulations will speedily form and unpleasant and embarrassing complications will surely occur. Then there is what is left of the osseous meatus, with the inner tympanic wall at its extremity. This must be kept firmly packed as granulations will spring up and occlude the meatal space, thus hindering and sometimes nullifying the results of a good operation. There is also a somewhat curving, gutter-like concavity, representing the aditus ad antrum, connecting the tympanic and antral cavities, in which exuberant granulations are likely to form, with their embarrassing consequences where great pains should be taken in the packing (Fig 40).

Fig 28—The Ballance flap showing curve of incision (After Ballance)

The general custom among surgeons is to pack these wounds with a single long strip of gauze, but in doing this I have found it impossible to accurately and firmly pack all the different sub-spaces as adequate pressure

of gauze in one place will move it from its position in another, and besides this, where so much gauze is being used in a continuous strip it is impossible to see just what is being done. I therefore (after the first dressing) use several pieces of gauze, which are separately packed into the different cavities. In the first place, a very small piece of gauze is packed into the gutter-like concavity connecting the tympanic and antral cavities. To do this accurately a small narrow-edged packer (Fig 41) is necessary, and for this purpose I employ an especially devised instrument, which is narrow, has a roughened edge and readily carries the gauze on its point. After this little pledget has been placed another small piece of gauze is packed against the inner tympanic wall. A longer piece

Fig 30—The Ballance flap (After Ballance)

may now be packed backward upward and inward into the antrum and mastoid space and firmly tufted into position with the bent packer so that no loose end drops down into the meatal space to obscure our vision. The remaining space may now be packed with gauze great caution being taken not to displace any of the previously placed pledgets. In this way all important cavities are firmly and permanently packed, the exuberant granulations rendered impossible.

how beautifully cases progress toward a speedy cure under this method of packing, and I urge on mastoid operators its faithful trial

The dressing should be repeated in two days and then again in two days, when the sutures should be removed. The original forceps as devised by Michel for the removal of metal sutures have flat surfaces on the inner aspects of the two jaws. It is, therefore, very difficult to engage the middle of the bent suture between the two blades, which is quite necessary in order to spread the two ex-

Fig 31—The Ballance flap
(After Ballance)

tremities of the suture so that the sharp points may be released from the flesh. I have, therefore, modified these forceps (Fig 24), making the upper jaw convex and the lower jaw concave, and roughening both inner aspects, which engages the suture and releases it much more readily. The dressings should be repeated every two days until the mastoid wound is firmly united, when the bandage may be discarded and the dressings, treat-

Fig 32—The Ballance flap (After Ballance)

ment, etc., carried on each day through the meatus. As soon as possible, or, in other words, as soon as the reasonably dry appearance of the parts will permit, the dressings should be made under dry conditions, and mopping the tissues with cotton or gauze should replace the process of irrigation, after which insufflations of xeroform or some other antiseptic dusting powder should be made before the gauze packing is carefully and firmly

replaced. Nevertheless, from time to time, mixed accretions will accumulate in the ear and necessitate thorough irrigation, followed by the use of some antiseptic solution, xeroform, etc., always, however, keeping the meatus firmly packed to the very end of the canal in order to maintain a capacious opening and prevent strictures. It is rarely necessary to keep such patients in the hospital for more than two weeks, after which they may present themselves at the office for daily treatment. In my experience these cases may be dismissed as cured in from ten to twelve weeks, some cases being cured in shorter time and some, of course, taking much longer. They should, however, all visit the surgeon four or five times

Fig 33—Needle for transferring graft to spatula.

Fig 34—A spatula for holding graft.

Fig 35—A stopper for coaxing graft into position.

a year to have the enlarged and irregular meatus thoroughly cleansed of cerumen, desquamated epithelium, etc., which, if allowed to remain, would ultimately produce an unhealthy condition of the parts. The remarks made by Dr. Dench of New York² on this phase of the results of the radical operation are so true and so comforting to both surgeon and patient that I take the liberty of quoting Dr. Dench's own words:

Even in those cases where the cure has been considered perfect, it is not uncommon to have the patients return, at intervals of from three to four months to one or two years, complaining of some discharge from the external auditory canal. An examination will show the entire cavity filled with a mass of desquamated epithelium, on the removal of which a small amount of pus may be found. If this accumulation has remained in the canal for a considerable period of time, desquamation of the epithelial lining of the cavity may have taken place, either completely or over certain areas. On removing the epithelial mass the cavity certainly looks far from healthy, and one unaccustomed to this condition would say that the radical operation had been a failure. If the cavity is simply sterilized with an alcoholic solution of bichlorid of mercury, and then dusted with some bland non-irritating powder, such as boric acid, xeroform, zinc oxid, or, in fact, any sterile powder, the cavity immediately becomes dry. In other words, the apparent relapse in so many cases is due simply to the fact that the integument lining the middle ear cavity and the mastoid cells, is improperly nourished. This integument forms the lining of a blind pouch where it is subjected to increased temperature, increased moisture, the absence of light, and no circulation of air, these latter conditions being essential to the proper nutrition of the normal skin. Moreover, it must be remembered that this tegumentary lining is applied closely to the bony walls of the cavity, with very little connective tissue substance intervening. It is not strange, therefore, that desquamation should take place from time to time, in such a cavity, and that the desquamated epithelium, if allowed to remain in position, should gradually accumulate until the cavity becomes completely filled with these epithelial cells. The pressure of these cast off cells causes superficial ulceration of the underlying

tissue, so that complete desquamation of a cavity of this kind frequently takes place. These attacks of desquamation of the cavity occur less and less frequently as time goes on, because the integument gradually adapts itself to its new habitat, and in the course of time is able to conform itself to its anomalous position. These attacks of desquamation should not be looked on as a recurrence of the otitis. As before stated, they are easily relieved by the removal of the epithelial detritus, and the sterilization of the walls of the cavity.

It should not be forgotten that in case of genuine cholesteatomatous masses having been discovered and removed it usually will be best to maintain, at least for a year or so, a permanent post-auricular opening by

Fig 36—The spatula placing the graft in position (After Ballance)

packing instead of suturing the mastoid wound. When thought desirable such openings may ultimately be closed by a simple plastic operation.

The surgeon is usually asked what will be the effect on hearing if a patient submits to the performance of the radical mastoid operation? In my experience, while a very few cases have suffered a diminution of the func-

Fig 37—The spatula has just been withdrawn (After Ballance)

tion of hearing, yet a great majority of my cases have either had their hearing improved or at least not impaired. It must be remembered that before the operation is performed serious pathologic changes in the tympanum have occurred, such as retracted ossicles, cicatricial bands, etc., all of which must surely impede the passage of sound waves to the labyrinth, and it is quite possible, and, indeed, in the light of experience, exceedingly probable, that a complete clearing away of these obstructive pathologic elements will be likely not only to not interfere with hearing, but to actually improve it

For some time past I have derived much satisfaction from the use of rotary burs (Fig 45) driven by the Victor electric engine (Fig 43). This engine is simple, strong, easily controlled and always ready, and I find myself using the engine more and other instruments less. While I never expect to depend on the engine alone, I believe it to be a most useful addition to our armamentarium.

I am aware of the fact that the radical mastoid operation is not popular with some surgeons who regard such

Fig 38—Commencing to compress the graft into the cavity (After Ballance.)

procedures as almost unwarrantable unless distinct and menacing operative indications are present. In other words, they do not advocate this operation for the relief of intractable purulent otorrhea, or at least apparently are never willing to admit the intractability of an aural discharge. For the benefit of such conservative surgeons I wish to close this article by a quotation from no less a man than Ballance³ of London, who makes use of the

Fig 39—The graft in position covered with gold leaf. C bone. E Graft. G Gold leaf (After Ballance)

following language, which, I am confident, will be substantially endorsed by most of the world's best otologists:

I have no longer any doubt that all cases of chronic purulent discharge from the ear should be treated by the complete operation, though I am aware that in some cases the disease has been rendered latent by the removal of ossicles alone or even by prolonged systematic dressing through the meatus. No ear potters with a chronic empyema because some few never recover with a single aspiration. It must be either war or peace. The lethal complications that we meet with are not

seldom the outcome of the stammering mind of Mr Ready-to-halt. The armed neutrality which promises operation if the need arises was, and is, the orthodox plan and has much to say for itself, but as Carlyle remarks, "The two internecine plans collapsing into one, that is the clearly fatal method." The great majority, if not all, of the chronic cases have commenced as an acute disease and it is an important practical question, how long may they be regarded as remaining so? That is, after what interval should the complete operation and not the so called operation for acute disease be performed? Many cases in which the operation for acute disease has been performed subsequently require the complete operation and I am now of opinion that in any case requiring operation after six weeks discharge the surer treatment is the complete opera-

Fig 40—Showing the completed mastoid operation and the cavities for packing. A, gutter like concavity connecting the attic and antrum representing the partially obliterated aditus ad antrum. B, promontory. C, antrum space. D, mastoid space. E, location of the facial nerve. F, fenestra ovalis. G, fenestra rotundum.

tion. The operation for acute disease is an incomplete procedure and therefore uncertain in its results, the bridge is not divided, the abscess is incised only at its two extremities, the narrow neck of the antrum provides only imperfect drainage, and is liable to become blocked by granulations. In cases of ingravescant appendicitis no surgeon would dare to call himself a late operator, but no one who has attended meetings at which the treatment of temporal bone disease has been debated can fail to be struck with the fact that the orators seem to plume themselves on avoiding operation. Is this a logical

Fig 41—Showing the narrow edged packer different sizes and shapes.

position to take up in treating a disease which is also in gravescent and which has perhaps a history of twenty years' standing, which may be tuberculous, and which in any case is liable to infect other parts of the body? The best results both to the hearing and to the health of the patient in suppurative temporal bone disease are obtained by early and complete operation. No surgeon would leave a sinus leading to diseased bone in the tibia for twenty years, or even for one, however cleverly he might be able to irrigate it or tickle it with antiseptic powders and cotton wool. In mastoid disease, as in Bunvan's allegory, the Messrs "Hopeful," who are persuaded to stray along the easiest going of By path Meadow, will not escape the crab-tree cudgel in the dungeons of Giant Despair."

72 Madison Street.

PULSUS PARADOXUS IN PERICARDITIS WITH EFFUSION

W J CALVERT, M.D.
COLUMBIA, MO

Pulsus paradoxus is one in which, during inspiration, the pulse becomes feeble or imperceptible. Since the time of Griesenger and Kussmaul pulsus paradoxus has been observed in a variety of pathologic conditions. F. Rigel¹ classifies these conditions as follows:

1 Mechanical interference with the large veins and aorta, as in Kussmaul's case. Here the heart is unaffected.

2 Obstructions in the air passage, causing an increased negative intra-thoracic pressure, which inhibits the heart's action.

3 Lowered activity of the heart.

Fig 1—View of organs from left side. a, Parietal pleura. b, left lung. c, aorta. d, superior vena cava. e, pericardium. f, collapsed superior cava. g, heart. The heart is curved as shown in Figure 2 so that this projection is much thicker than the heart really is. h, right auricle. i, collapsed inferior cava. j, inferior vena cava. k, right cupola of diaphragm. l, central tendon of diaphragm. m, left cupola of diaphragm.

Pulsus paradoxus is a distinct variation from the normal, consequently it is pathologic and must have a cause. As pulsus paradoxus has been observed in a variety of conditions, its causes must vary, but in each condition this cause should be constant. From a clinical point of view pulsus paradoxus should be a sign of the existence of its cause, and the importance of this sign must depend

on the nature of the pathologic condition. From a diagnostic point of view pulsus paradoxus is not of especial differential importance, but as it does not exist throughout the entire course of a given clinical picture, pulsus paradoxus heralds the development of a stage in the clinical course of a disease.

Recently I have had an opportunity to study the cadavers of two individuals who had pericardial effusion at the time of death, and in this paper I shall attempt to show the physical explanation of pulsus paradoxus and its significance in cases of pericarditis with effusion. The material for this paper was obtained from Dr. C. M. Jackson, to whom I wish to express my thanks.

Fig 2—Transverse section of body showing flattened condition of the heart (A) and its relation to the pericardial wall (B)

The cadavers were injected with formalin and allowed to harden, after which they were transversely sectioned. Drawings and measurements of the sections were made while the material was fresh. From these data the several organs were projected as shown in the figures. By this method the position of the organs at the time of death was preserved and have been faithfully projected.

CASE 1—The cadaver is that of a fairly well built male negro, aged 30. On examination, left sided pleurisy with a very small effusion, adherent right pleurisy and pericarditis

Fig 3—Section showing the superior portion of the pericardial sac and the collapsed superior vena cava through which has been passed a piece of paper

with effusion were observed. In Figure 1 the general relationship of the organs is very well shown. Only those points of immediate interest will be described.

The heart (Figs 1 and 2) and the superior cava (Fig 1, d) are both collapsed, and the lumen of the superior cava is

shaped (Fig 1, f) from the point where it enters the pericardium to the right auricle. In Figure 3 is seen a piece of paper that has been passed through the vein from above. The superior cava above this constriction was distended with blood.

The inferior cava is collapsed (Fig 1, i). In Figure 4 a piece of paper has been passed through the vein from below. Below the collapsed portion the vein was distended with blood.

CASE 2—Cadaver is that of a male negro, aged 29, well formed and fairly well nourished. Examination revealed tuberculous consolidation, with a small cavity formation in the left lung, and pericarditis with effusion. In amount the effusion was about the same as in Case 1. The relative displacement of organs is also similar to Case 1. The heart however, and venæ cavae are greatly distended (Fig 5).

In the first case the venæ cavae within the pericardial sac are collapsed, in the second case distended. The conditions here are flexible walled tubes (venæ cavae) passing into and partially through a distended sac, the walls of which are flexible and elastic (pericardium), consequently the degree of distension of the veins must depend on the relationship between the intravenous and intrapericardial pressures. If the venous pressure is greater the veins must be distended, if less, collapsed. But if the pericardial pressure is sufficient to collapse the veins no blood can enter the heart and death must

Fig 4—Section just above the entrance of the inferior cava into the pericardial sac. A piece of paper has been passed through the collapsed lumen. In front of the paper the depression of the pericardial wall into the distended vein is well shown

follow. During life, then, the pericardial pressure must remain below that in the veins. If the venous pressure is sufficient to distend the veins a relatively normal amount of blood will flow to the heart.

The pericardial sac is larger than the heart contained therein, consequently a small quantity of fluid may collect in the sac without materially changing the pericardial pressure. But if the fluid continues to collect, the pericardium must be more or less distended and the pericardial pressure positively increased. Owing to the negative, or slightly positive, pressure within the veins a relatively great effect is produced on them by a small increase in the pericardial pressure. This increase in pericardial pressure must in a proportionate degree constrict the venæ cavae (stenosis of venæ cavae). This constriction must obstruct the flow of blood through the veins, producing a congestion and rise in venous pressure. This rise in venous pressure causes the blood to either dilate the venæ cavae to the normal or to flow faster through the constricted portion. With each increase in the

dial pressure the veins must be further compressed or obstructed, producing additional congestion and rise of venous pressure. This process must continue until the limit of venous congestion and pressure is reached.

As the venous pressure changes during inspiration and expiration, there is at all times a maximum and minimum venous pressure. The pericardial pressure must be lower than the minimum pressure or the veins must be closed during the period of lowest pressure. This procedure would cause additional congestion and a rise of venous pressure above that in the pericardium.

The thick, strong pericardial wall, when distended by a pressure almost as great as that within the veins, can not be influenced as easily as the thin walls of the veins by the respiratory change in intra-thoracic pressure. Consequently the pericardial pressure remains during inspiration and expiration more constant than the venous pressure.

approach the venous pressure. As it rises it must pass the minimum venous pressure to remain for a time at various points between the maximum and minimum venous pressure.

Whenever the pericardial pressure is greater than that in the veins the latter must be constricted or collapsed. The degree of constriction must be determined by the difference in pressure. The flow of blood to the right heart must decrease proportionately to the constriction of the veins, as further rise in venous pressure is impossible. The lower venous pressure is during inspiration. Consequently, the greatest constriction of the veins occurs, and the minimum quantity of blood flows to the heart, during inspiration. During expiration the venous pressure rises above that in the pericardium, the veins are dilated and the maximum quantity of blood flows to the heart. This maximum (expiratory) and minimum (inspiratory) flow of blood to the heart must

Fig. 5.—Section through lower portion of pericardial sac. The conglutinated fluid surrounds the lower portion of the heart. To the subject's right is seen the lower portion of the distended right auricle and inferior vena cava.

The venous congestion and rise in pressure become a compensatory congestion and a rise in pressure to compensate the pericardial pressure in exactly the same sense as the left auricle dilates and creates additional pressure to compensate a stenosis in the mitral opening, and as such must be subject, in a measure, to the same laws of reserve forces and broken compensation to which the heart chambers are subjected.

When the limit of venous congestion and pressure has been reached each rise in pericardial pressure is not followed by a rise in venous pressure, the veins begin to fail to compensate the pericardial pressure, and there develops a broken compensation in a compensatory venous congestion. The pericardial pressure may now

continue while the pericardial pressure remains between the maximum and minimum venous pressures, or during the stage of broken compensation in the venous congestion.

The amount of blood entering the right heart must determine the condition of the pulmonary circulation, and this in turn determines the condition of the general circulation. The diminished amount of blood during inspiration gives lowered arterial tension—rapid and small pulse. The increased expiratory amount of blood gives a rise in arterial tension—decrease in pulse rate and increase in volume. This is the pulsus paradoxus. As the pericardial pressure approaches the maximum venous pressure the degree of pulsus paradoxus increases.

Pulsus paradoxus in pericarditis with effusion is caused by broken compensation in a compensatory venous congestion. If this is so pulsus paradoxus is a sign of broken compensation in the venous congestion, and denotes the time when the pericardial pressure must be reduced or death may at any time follow—due to constriction of the venæ cavæ beyond the point when sufficient blood to maintain life can enter the right heart.

Pulsus paradoxus should appear relatively early in cases with thick, strong pericardial walls, and relatively late in thin, elastic pericardial walls.

SUMMARY

- 1 Pericardial effusion produces stenosis of the venæ cavæ
- 2 This stenosis is relatively compensated by a rise in venous pressure
- 3 This compensation fails when the pericardial pressure is greater than the venous pressure
- 4 Owing to respiratory change in venous pressure the degree of broken compensation varies in inspiration and expiration—greatest in inspiration, least in expiration
- 5 The variation in compensation carries varying quantities of blood to right heart (and to general circulation)—least in inspiration, greatest in expiration.
- 6 The respiratory variation in quantity of blood passing to general circulation is sufficient to explain pulsus paradoxus

NOTE—Since writing the above article Franke² calls attention to venous and hepatic compensation in cases of tricuspid insufficiency, and likens their action to that of the right ventricle in mitral lesions—W. J. C.

DRAINAGE OF THE HEPATIC DUCT,

CONSIDERED ESPECIALLY IN SERIOUS INFECTIOUS PROCESSES OF THE LIVER

CHARLES GREENE CUMSTON, M.D.
BOSTON

In a recent paper¹ relative to the advantages of surgical treatment of biliary infection resulting in hepatic cirrhosis, I pointed out that the large number of cirrhotics represented the last stage of an irritative process in the liver and were in reality chronic hepatites originating from infection. Biliary cirrhosis is at the present time considered as infectious radicular angiocholitis, either subacute or chronic, and consequently it is quite logical to treat the pathologic condition like any infectious angiocholitis, in other words, by drainage of the gall bladder in order to give exit to the septic bile. In order to obtain a successful outcome, however, the drainage should be instituted at a time when the hepatic cell has not been destroyed by a sclerous process resulting from the infection. On the other hand, a new conception has come to light which accords to infection a part in the pathogenesis of vascular cirrhosis, consequently it is logical to foresee that drainage of the gall bladder will be the method of choice, because it seems to be favorably act on the intrahepatic venous circulation. As the title of this paper indicates, the question of drainage of the hepatic duct will be considered particularly from the standpoint of serious infectious processes of the liver either arising from calculi or other sources. The question of drainage is indicated when there is possibility of

large retention, because it has been amply proven that when there is an obstruction of the principal biliary tracts retention of bile follows with an increase in size of the liver and dilatation of the hepatic duct, which renders drainage from this canal fairly easy to realize. Drainage of the hepatic duct does not appear any more complicated than other surgical interferences on the biliary tract and, although in some instances it may be difficult, the excellent results that it has given should encourage surgeons to continue in this direction and to employ it systematically in every case where it is indicated.

As to the technic of drainage of the hepatic duct, there are three principal methods along with a few others which may be considered as possessing special applications. In the first place, we have drainage of the cystic duct and gall bladder. The latter having been opened a drainage tube is introduced through the dilated cystic duct down to the hepatic duct, in other words being complementary to a cholecystostomy. In the second we have drainage by the choledochotomy after incision of the duct, the drainage being carried down to the common bile duct. Both of these procedures may be performed either by the open or the closed method, as distinguished from the third procedure, which would call for the drainage of the hepatic duct by means of a cannula inserted directly into the duct. The first method is the simplest and is the one which I have employed in the majority of cases. It is performed by making an incision in the abdominal wall over the gall bladder, opening the gall bladder, and passing a drainage tube down the cystic duct into the hepatic duct. The second method is performed by making an incision in the abdominal wall over the gall bladder, opening the gall bladder, and passing a drainage tube down the cystic duct into the hepatic duct. The third method is performed by making an incision in the abdominal wall over the gall bladder, opening the gall bladder, and passing a drainage tube down the cystic duct into the hepatic duct.

the rectus, in other words, about on the level with the umbilicus. In this way the fibers of the rectus muscle are cut obliquely through at their internal half by the intermediary line of incision, but the external half of the muscle remains intact. This incision gives an easy access to the entire biliary tract, while at the same time section of the rectus, being only partial, facilitates the repair of the abdominal wall. Oblique incision parallel to the border of the ribs, vertical, median or lateral incisions with perpendicular section of the rectus have also been proposed, but in reality it would appear that these incisions, although fairly good, do not give the same facility as the one devised by Kehrer. To my mind, however, the most important point is the use of the pillow as recommended by Mayo-Robson, the nature of the incision being of lesser importance.

When the abdomen is opened, the hepatic canal is sought for, a broad retractor being placed under the lower border of the liver, which should be pushed up under the ribs as much as possible, while a second retractor pushes the left border of the abdominal incision downward and to the left, including the transverse colon and duodenum. Gauze sponges should be placed under and around the retractors to protect the peritoneal cavity from biliary infection. The gall bladder is first examined and if found distended is easily exposed, but if the organ is retracted it may be quite hidden by adhesions. Following the lower aspect of the gall bladder, when it has been exposed, the cystic duct is felt, and by following this canal the fingers will reach the hiatus of Winslow, which is often very difficult or perhaps even impossible to recognize on account of adhesions uniting the gastrohepatic omentum to the posterior layer of the minor omental cavity. If one can penetrate the hiatus, nothing is easier than to seize the gastrohepatic omentum between the fingers and its upper part and to explore the hepatic duct in order to directly operate on it. Usually, however, in the cases under consideration, with a long history of angiocholecystitis, it is impossible to recognize the hepatic duct in the midst of the adhesions. Under these circumstances one should, so to speak, endeavor to work down on it through the adhesions, although this must be undertaken with great care on account of the close proximity of the portal vein and hepatic artery. If it is then found that it can not be exposed recourse may be had to the endocholecystic route, that is to say, after having opened the gall bladder down to the cystic duct, a catheter is gently inserted downward so that it reaches the desired region of the biliary tract. When the hepatic duct has been exposed it should be incised in order to remove any calculi that may be present in cases of lithiasis, after which a drainage tube is introduced. It should be remembered that one is working deep down nearly at the level of the hilum and if the retractors are properly placed, with the liver well raised, one should endeavor to exteriorize the hepatic duct with the fingers. When a good hold can be made on it, its wall should be freely exposed by prudently breaking down all surrounding structures with a director, and, if a calculus is present, the incision should be carried directly over it. When it has been made certain that there is only one calculus and if infection is absent or slight, the incision may be closed on the condition that drainage of the gall bladder is carried out, on the other hand if the markedly infected aspect of the patient indicates a decided septic condition of the bile, or if there is any fear that other calculi may be present at the point of origin of the branches of the hepatic duct,

direct drainage of the latter should be instituted. As this paper particularly refers to these cases, I will briefly describe the manner in which this drainage should be carried out.

A rubber drain proportionate to the caliber of the duct and which may be easily inserted in its lumen is placed in the upper part of the hepatic duct, being inserted to the extent of one or two centimeters and for security, united with fine catgut to the borders of the incision in the duct, its other end being brought out through the abdominal incision. By this procedure it is almost certain to drain away all the bile, the tube being surrounded by some strips of iodoform gauze to protect the peritoneum against any possible escape of bile, the gauze being removed at the end of 48 hours. A long tube without any perforations should be brought out through the abdominal dressings and placed in a receptacle containing some antiseptic fluid, thus creating a real siphon action, bringing all the bile outside, and by this means a perfectly absolute drainage results. If one chooses, however, the end of the drain may simply be surrounded in the abdominal dressings, which, when saturated, should be changed. No absolute rule as to the time that the drain should be allowed to remain can be formulated, because everything depends on the patient's general condition, the rapidity with which the secondary elimination of calculi takes place, as well as the degree of infection of the bile. It may be said, however, that when the adhesions have become solid, that is to say, at the end of a week, the tube may be removed and the bile allowed to escape through the fistulous tract thus formed. Should the bile be very thick thus tending to obstruct the lumen of the tube, irrigation through the latter should be resorted to, which dilutes the secreted liquids and may also wash out small calculi which have remained at the upper part of the hepatic duct. Later on, the tube may be removed each time that it needs to be cleansed and when it has been definitely removed the fistula should be irrigated once daily. The final removal of the tube should be done only when the bile has become perfectly transparent and fluid and the patient's general condition has sufficiently improved with complete absence of any rise in temperature.

Considering now the technic of indirect drainage of the hepatic duct, I would say that I will not insist on that made by way of the ductus choledochus, because it merely represents an easy complementary procedure of choledochotomy, an operation which at the present time has become classical and currently undertaken. Drainage of the choledochus and consequently of the hepatic duct may be accomplished by a drain placed in an incision made in the former, but this is not, properly speaking, drainage of the hepatic duct. After having done away with the obstruction to the flow of bile, which is usually a calculus, and being assured that there are no others located higher up, a tube, introduced through the incision in the choledochus, is pushed as far as possible into the hepatic duct, and this is facilitated from the fact that the caliber of the latter duct is greater below than above and, on the other hand, from the fact that it is always dilated when any obstruction of the choledochus exists. The drain which should be pushed, if possible up to the hilum, is held in place and surrounded with strips of gauze protecting the peritoneum from the exit of bile around the tube. Concerning drainage of the cystic duct and gall bladder two cases can be considered. I will not refer here to cholecystostomy, pure and simple which is a very excellent method of drain-

age, but I would say that it can not give rise to a real drainage of the hepatic duct. This drainage is done after having either opened the gall bladder and sutured it to the abdominal wall or after having performed cholecystectomy. In both cases the gall bladder is carefully explored, after which the bile ducts are likewise treated and the proper technic carried out according to circumstances. If the gall bladder and cystic duct are dilated on account of the presence of calculi in the latter, the gall bladder is sutured to the abdominal wall and the drainage tube introduced down to the neighborhood of the hilum by way of the dilated cystic duct and, when properly in place, all bile coming from the liver is carried out just as if the tube had been introduced into the hepatic duct itself.

Although this means of drainage is excellent in many respects, it does not prevent the possible flow of bile toward the choledochus and a continuation of the infection when the bile is particularly septic. In point of fact, it is the spur present at the point of intersection of the cystic and hepatic ducts which is the obstruction to the formation of a perfect drainage of the hepatic duct and it is this obstacle that must be done away with. If the cystic duct is patent, a narrow-bladed knife may be introduced into its lumen, passed along the groove of a director and the spur cut through, after which a tube may be pushed down into the hepatic duct. If the gall bladder and cystic duct are shriveled up and permeable with difficulty, cholecystectomy may be done, and, by using the remains of the cystic duct as a guide, one may slowly incise the structures until the hepatic duct is reached, which is, in its turn, opened, the calculi contained within it removed, and the drainage tube introduced. The latter should be always surrounded by strips of gauze to prevent peritoneal infection from the bile. In all these cases of drainage by the choledochus or the accessory biliary tracts, after cholecystectomy, or by the way of a dilated cystic duct, the after care is the same as that employed in direct drainage of the hepatic duct, so that it is unnecessary to refer to them.

The various means of drainage that I have so far mentioned may be considered as classical, but I should like to refer in a few words to the more or less exceptional procedure that the surgeon may occasionally be obliged to adopt. It may happen that following an obstruction of the choledochus the hepatic duct becomes greatly distended forming a true cystic tumor projecting through the hepatic parenchyma similar to a hydatid cyst, or in the midst of adhesions which partially conceal it, may simulate a distended gall bladder under the lower border of the liver. Such diagnostic errors occur and are excusable and they are very interesting to study, because, when known, error in treatment may be avoided and the surgeon will at once directly attack the hepatic duct or at least incise the choledochus in order to remove the obstruction and indirectly drain the hepatic duct by this route. Hepaticostomy may be accomplished by two ways, viz the transhepatic and the infrahepatic route. In both cases, as the name indicates the duct is opened and stitched to the cutaneous incision. The first instance of transhepatic hepaticostomy was done in 1888 by Thornton. The case was an enormous dilatation of the hepatic duct by bile and numerous calculi, so that it formed a pocket causing the anterior aspect of the liver to project forward and communicated with the choledochus. Similar other cases have been met with by Mayo-Robson and others. The difficulty of an exact diagnosis of such lesions is evident both

from the standpoint of its nature as well as site, because very frequently only a slight projection on the surface of the liver is noticed, or even a mere change in color is the only indication. In the first place, the exact point of hepatic parenchyma to be incised should be thoroughly mapped out in order to have all necessary facility for treating the contents of the cyst formed by the distended hepatic duct. The most important point is the condition of the choledochus and the surgeon should give particular attention to this because the technic followed will entirely depend on the patency of this duct, and consequently before making an incision into the liver the biliary tract should be carefully explored.

If one is certain that the duct is patent, after having removed the cause of obstruction, and that the flow of bile is normally accomplished, hepaticostomy may then be undertaken, the liver having been in the first place sutured to the parietal peritoneum. On the other hand if the duct is not patent, the opening made in the hepatic duct should be sutured to the abdominal incision. With whichever case one is dealing, when the pocket has been incised and fixed to the incision, a careful exploration should be made particularly on the terminal end of the hepatic duct and the origin of the choledochus, at which point the obstruction must necessarily be found, and the exploration should be continued until there is absolute certainty that the obstruction has been removed. If, by chance, the dilatation arises in one of the primary branches of the hepatic duct, there is really no change in technic. A large drainage tube should be inserted in the pocket and the after-care consisting of irrigation of the pocket, should be carried out as in any similar operation.

Infrahepaticostomy dates back to 1899 but the first operation was not successful. The hepatic duct was greatly dilated, forming an enormous intrahepatic cyst. At autopsy it was found that the distension involved the choledochus and hepatic duct, but the cause remained undiscovered. These two exceptional technics have certainly very distinct indications in some cases, but as yet instances where these have been done are far too few for one to make any conclusion relative to their value.

Drainage of the hepatic duct has for its end to temporarily give exit to bile directly from the principal biliary passages, especially when there is an infection of the organism resulting from some infectious process of the liver. Such drainage is absolute because it is established in the hepatic duct at its exit from the liver and, if it is well carried out, the bile can neither reach the duodenum nor the gall bladder. Now, since all the bile is drained away, the drainage should only be temporary, because the organism can not be continually deprived of the bile, or, more properly speaking, the small intestine is not able to get along without such a necessary organic fluid for the digestion. Although temporary it is a precious surgical resource to thus be able to remove from the body the poisons secreted by the hepatic cell and which otherwise would be carried to the intestine by the choledochus and thus continue to poison the organism. Like all new methods this one has been the object of numerous objections such as suppression of the biliary function, diminution of the caliber of the hepatic duct and irritation of the walls of the duct as well as the possibility of hemorrhage. It is evident that the total elimination of the bile externally is an important consideration but when the organism is already infected from a septic bile temporarily deviate its course then

general infection of the subject. As to the decrease in the caliber of the hepatic duct there is nothing easier than to remove the drain in order to irrigate. Consequently such an objection is really of little value. There is, however, one of far greater import, viz., whether the lumen of the hepatic duct is always sufficiently large to allow of the introduction of the drainage tube. It has, however, been amply shown by Delageniere that each time an obstruction is seated in the choledochus resulting in biliary retention with an increase in the size of the liver the hepatic duct is always found dilated and consequently presents the best possible condition for drainage. When the choledochus is obstructed by calculi it is practically certain that the gall bladder will be found atrophied and the hepatic duct dilated. It is not, however, only lithiasis that produces this dilatation, because every time that some cause, such as a mechanical obstruction or infection results in biliary retention with increase in size of the liver, the hepatic duct will be found dilated, and this very dilatation is, so to speak, an indication to establish total drainage. If the gall bladder and cystic duct are used to obtain drainage by simply performing cholecystostomy, it is never certain that the cystic duct is patent, as even in the normal state it is not regular in caliber and when pathologically affected is more apt to be reduced in size, deformed and more or less obliterated. On the other hand, choledochotomy with the introduction of a drain in contact with the incision of the duct and packing with gauze is of necessity insufficient and does not prevent quite an amount of septic bile reaching the terminal portion of the choledochus and entering the duodenum, thus keeping up the sepsis. This, however, does not necessarily mean that total drainage should be systematically employed, because in medicine, as in surgery, there should be no fixed rules and everything should be subordinated to circumstances, for each case requires a particular treatment.

Before considering the general indications for total drainage of the hepatic duct it should be mentioned that, according to the observation of most operators, obstruction from calculi in the primary branches of the hepatic duct and which have been impossible to extract are thus given an easy exit, but it is more especially a marked infection of the liver, whether it originates from calculi or some other cause, that total drainage is indicated, because by this means alone all the bile is removed.

Without referring to the exceptional technics it may be said that one may drain by way of the accessory biliary tracts, by the choledochus or the hepatic duct itself, and we would now consider the indications and contraindications of each of these procedures. We will first consider indirect drainage of the hepatic duct by way of the gall bladder and cystic duct. Cholecystostomy can not be properly considered as true drainage of the hepatic duct, because, unless there is an absolute occlusion of the choledochus, nothing prevents the bile from reaching the intestine. The introduction of a drainage tube through a dilated cystic duct and carried deeply down is certainly a step forward, but this method, although assuring an almost absolute derivation of the bile outward, is subject to the same objection already mentioned. It is consequently to drainage by a tube reaching down to the hepatic duct that we should consider, and its indications are practically as follows. A serious non-calculous infection is a certain indication, but it is cholecystitis that especially requires this treatment, because the presence of calculi in the gall bladder and

cystic duct requires direct surgical treatment of these organs, and this is what has always been done until recently when one has introduced a tube down to the hepatic duct by way of the accessory biliary tracts after having performed the ordinary operations, such as cholecystostomy, cholecystectomy, and so forth. Serious infection of the liver and biliary artery have rendered necessary this supplement to the surgery of the gall bladder, in spite of its difficulties, because all the bile coming from the liver should be drained away by an introduction of the tube into the hepatic duct itself, and, since the gall bladder has been opened, one should profit by the cystic duct to insert a drain down to the hepatic, and, according to circumstances, the dilated cystic duct can be used for the introduction of the tube after incision of the spur already alluded to, or the remains of the cystic duct may be used as a guide to reach the hepatic duct, incise it and introduce drain. Here the indications are made evident by the pathologic lesions more than by the clinical history of the case. Total drainage may be either temporary or permanent, according to whether one is dealing with a serious infection with patency of the choledochus or with an occlusion of this duct which can not be removed, or when an interference with the deeper tracts is incompatible with the general condition of the patient or contraindicated by the existing lesions.

As to drainage by way of the choledochus, it may be said that in reality this is merely a direct drainage of the hepatic duct. Formerly a drainage tube was simply placed in contact with the incision made in the choledochus, or inserted within its lumen, but at the present time the tube is pushed down to the origin of the hepatic duct, when the following conditions are present. The principal indication is the presence of a calculus at the origin of the choledochus, whose presence has set up a serious infection of the liver, but, when once the calculus has been removed, the duct is found free on account of the dilatation which has taken place in the hepatic duct and all that is necessary is to introduce the drainage tube, pushing it up to the hilum of the liver. Beside infection, which is the principal indication for drainage, the presence of suspected calculi at the origin of the hepatic duct should also be called to mind. Direct drainage of the hepatic duct is of more recent date, its indications being serious infection and the suspected presence of calculi in the region of the hilum of the liver. These indications are the same as those for drainage of the choledochus and consequently it is only done after removal of the calculi lodged in the hepatic duct. I have referred to the objections which have been made to this method, but I may add that it is not an obligatory supplement to hepaticostomy, because, if no serious infection is present, if the patency of the hepatic duct at the hilum is certain, if, on the other hand, it is impossible to re-establish the course of the bile either by way of the choledochus or the gall bladder, hepaticocenterostomy may be resorted to.

Cancer and Climate—The *Med. Klinik* for February 24 quotes from a recent publication of the Amsterdam board of health giving the statistics of cancer in various cities and climates. The figures show that climate seems to have no influence on the prevalence of cancer. The report states that during 1905 Copenhagen recorded 154 deaths from cancer to 100,000 inhabitants. Florence 140, Chicago, 50, Nice and Turin 72 and 74, Tokio, 57, Naples, 54, Stuttgart, 136, Zurich, 139, Lyons, 171, Cracow, 209, Berlin, 115, Paris, 114, London, 100, and Dresden, 105.

SOME WELL-KNOWN SYNTHETIC CHEMICALS
AND THEIR RELATION TO THE PURE
FOOD AND DRUGS ACT *

LYMAN F. KEBLER, Ph C, M D

Chief of the Drug Laboratory Department of Agriculture, Member
of the Council on Pharmacy and Chemistry, American
Medical Association
WASHINGTON, D C

The word "synthetic," as used in the chemical world, means a combination of separate substances, elements or radicals, which result in the formation of definite chemicals. The manufacture of acetanilid from benzol, or antipyrin from anilin, affords good illustrations, inasmuch as in the manufacture of both several operations are necessary. The word "synthetic," however, has acquired an entirely different meaning, which has been used to a considerable extent in the past, usually in an honorable manner, but often for the purpose of deceiving not only the public, but physicians as well. This feature has been claiming recognition in no unmistakable terms during the past few months. It is held by some that the mixing together of the various cinchona alkaloidal salts, in proportion as found by analysis of the cinchona barks, the same dissolved in simple elixir and colored with caramel, is a "synthetic elixir of cinchona bark." Other illustrations are the common headache mixtures, which consisted in the past, and at present to a lesser extent, chiefly of acetanilid, sodium bicarbonate or ammonium carbonate and caffeine. These mixtures are at times so named as to lead to the belief that they are synthetic chemicals. In some cases a hypothetical chemical name, together with a structural formula, is attached to make the deception even more complete. Since the passage of the act the acetanilid has been replaced in many instances by para-acetphenetidin (commonly known as phenacetin) and antipyrin. This subject will be considered in a subsequent portion of this paper. It is also claimed that a so-called raspberry extract, made by dissolving various esters in alcohol (grain or wood) and coloring the solution with cudbear, is a "synthetic raspberry extract." There are undoubtedly different views as to whether or not the latter claims are justifiable, but in my opinion the first definition, or a similar one, is the only one that should receive any recognition in the chemical world. As a matter of fact, the latter is simply used to attract the attention of the public and has no basis for existence whatever.

The Food and Drugs Act specifies that an article is misbranded if it fails to bear a statement on the label of the package "of the quantity or proportion of any alcohol, morphin, opium, cocain, heroin, alpha or beta eucain, chloroform, cannabis indica, chloral hydrate, or acetanilid, or any derivative or preparation of any such substances contained therein." The act also forbids the use of any poisons or deleterious ingredients in the manufacture of food products or of any agent which misleads or deceives in any particular. The two phases of the act just considered require first, that the presence of certain habit-forming drugs shall be declared on the label and, second, that no injurious agent or agents which deceive in any particular shall be used in the manufacture of food products.

It can readily be seen by chemists familiar with the ingredients enumerated in the act that the phrase "derivative and preparation of same" is very comprehensive

which was undoubtedly the intention of Congress. This clause was undoubtedly introduced for the purpose of preventing or evading prosecutions under the law on pure technicalities. For example, it has been held by the defendant in a number of cases in which a prosecution was brought, on the ground that a product contained the forbidden ingredient morphin, that the ingredient in the product under consideration was not morphin but morphin sulphate. The same position has been taken in other cases, for example, it is contended by some manufacturers that a preparation in which cocain is introduced through the medium of an extract of coca leaves or by extracting coca leaves directly with the menstruum of the article, can not be considered a cocain preparation any more than could coffee be construed as a caffeine product. It is immaterial how cocain is introduced into a product, the fact of its presence renders such a product a cocain preparation. Any other conclusion must be based on a technicality or is a mere quibble.

So far as the word "preparation" is concerned as used in the act, there does not appear to be any question relative to its meaning, but this is not the case with the word "derivative." The term "derived from" as used in the tariff law of 1897 has not only been subject to decisions at the hands of the appraiser of the United States Customs Service, but has also been defined by the United States Federal Court (1899 Federal Reporter 719) and the United States Court of Appeals (102 Federal Reporter 603). The decisions arrived at are that the words "derive," "derivation," "derivative" must be interpreted as "made of," "prepared from," "produced from," "obtained from," and that the term "derived from" has its ordinary meaning of "produced from" and relates to the physical substance from which such product is obtained and not to its chemical relationship. In other words, if the manufacturer starts with alizarin and by partial replacement produces a dye such dye is derived from alizarin, but not otherwise. The question under consideration in the above decisions was whether or not certain dyes were derived from alizarin. These precedents must undoubtedly be taken into consideration in connection with the recently-enacted pure food and drugs law, but the aims and objects of the latter are entirely different from those of the tariff law.

The meaning of the term "derivative" as used in the act, has been called into question because (para) acetphenetidin is classed as a derivative of acetanilid. There is no question but that (para) acetphenetidin is a derivative of acetanilid both chemically and physiologically and resembles it in its tendency to habit formation, physiologic action and physical properties. Furthermore treasury decision 13270 construes this chemical as an alcoholic medicinal preparation. The exact status of this product under the law appears therefore, to be in a somewhat unsettled condition at present.

In this paper only a few of the synthetic chemicals that are affected by the Federal Law will be considered. For the purpose of ready reference it is deemed desirable to collect them into the following groups:

Common names	ALCOHOL GROUP
	Synonyms and Chemical names
Ether	Sulphuric ether, ethyl ether
Ethyl acetate	Acetic ether
Ethyl nitrite	
Ethyl bromid	Monoethyl bromide
	CHLORINE AND CHLORAL HYDRATE GROUP
Chloroform	Trichloromethane
Chloral hydrate	Trichloroethylidene glycol
Chlorotone	Ammonium Chloride
	Chloral alcoholate
	Trichloroethylidene glycol

* Lecture delivered before the Chemical Section of the Franklin Institute Jan 10, 1907

	LOCALIN GROUP
Alpha eucalin	Benzoyl methyl tetra methyl gamma-oxy piperidin-carboxylic methyl ester
Beta-eucalin	Benzoyl vinyl-diacetonalkamin hydrochlorid.
	OPIMUM MORPHIN GROUP
Heroin	Diacetyl morphin.
Dionin	Ethyl morphin hydrochlorid
Peronin	Benzyl morphin hydrochlorid.
Codein	Methyl morphin
	ACETANILID GROUP
Acetanilid	Phenylacetamid antifebrin
Phenacetin	Para acet phenetidn, Acetphenetidn
	Para acet amido phenetol,
	Para-ovyethyl acetanilid.
Antipyrin	Analgesin Anodynin Parodyn Phenazon,
	Phenyl-dimethyl pyrazolon, Pyrazin
	SWEETENING AND FLAVORING GROUP
RESERVATIVE	
Salicylic acid	Ortho-oxy benzoic acid.
Benzoic acid	
Vanillin	Methyl protocatechuic aldehyd
Saccharin	Benzosulphind

In these groups it will be noticed that not only are the common names employed, but also the synonyms and structural formula names. The object of giving the latter is simply to call attention to the fact that manufacturers are making frequent requests to be permitted to use some other words than those specifically enumerated in the act, for example, one manufacturer represents that a setting forth on the label of the fact that his product contains opium would be a financial loss, and asks whether it would not be satisfactory to state on the label that this product contains a certain amount of papaver somniferum. Other manufacturers request that they be permitted to use the word phenylacetamid or the phrase "the monacetyl derivative of anilin" or the structural formula in place of the word acetanilid. If it were permitted to use other words than those given in the act for the ingredients specifically covered there would soon be such a confusion of names and structural formula that it would be necessary to consult an expert organic chemist to decipher them.

It is held by some writers that it was absolutely unwarranted to include some of the chemicals and products enumerated in the rules and regulations, because in many cases such articles are never used as habit-producing drugs. In this connection it should be stated that this question was submitted to about twelve of the best pharmaceutical chemists, manufacturing and analytical, and while a few think that the public would be protected just as well without requiring a declaration on the label of the presence of certain drugs, yet on the whole every one heard from thus far suggested that additional products be included. In other words, the suggestions of these men indicate that instead of having included too many drugs the list should be augmented. Our general correspondence confirms this attitude. It should, furthermore, be noted that it seems necessary to include certain chemicals in order to avoid technicalities, for example, it is held by one chemist that a certain chemical could not be considered a derivative of alcohol because ethyl bromid is not enumerated as a derivative of alcohol in the regulations, and inasmuch as this chemical is employed directly in introducing the ethyl group into the product it is necessary that this product be included as a derivative of alcohol. The contention that certain ingredients are not used as habit-producing drugs is not well taken. This claim is made for ether, which, as a matter of fact however is used to fortify beverages in order to render intoxication more rapid and complete particularly in this case with individuals addicted to the alcohol habit and whom the ordinary beverage does not appear to satisfy.

The morphin group presents some interesting features. It is well known that morphin and opium and the dis-

astrous results of their use have been widely exploited during the past few years, not only in the lay journals, but also to some extent in the public press. Many manufacturers deem it expedient to remove these words from their labels if possible because of this unfavorable notoriety. The result is that in many instances these ingredients have been replaced with other products which are not so well known to the public, for example, heroin, codein and diomin have replaced morphin in a considerable number of cases. These chemicals are at present supposed not to produce such deleterious results on the human system as do opium and morphin, even when used over extended periods, but it is difficult at present even to conjecture what their promiscuous and indiscriminate use will bring forth in the future. It is even now reported that where narcotic laws prohibit the indiscriminate sale of morphin and no restrictions whatever are placed on the sale of codein the latter product is being used in place of the former.

What has been said in connection with the opium-morphin group applies equally to the acetanilid group. At the time the Food and Drugs Act was passed there were approximately 500 headache and laxative preparations which contained acetanilid sold through the jobbing trade under various names. It is a significant fact that the acetanilid in many of these preparations has been replaced by acetphenetidn (phenacetin), and we are also informed from various sections of the country that antipyrin is being employed for the same purpose. Exactly why some of these changes have been made is not clearly apparent, because none of the substitutes are as cheap as acetanilid, although the price of each has been materially reduced within the past few years. This is due largely to the fact that the patents covering these chemicals have lapsed, and the price has fallen in the case of acetphenetidn (phenacetin) from \$16.00 to \$1.00 a pound, and in the case of antipyrin from about \$22.00 to \$2.40 a pound, both in bulk. The price of acetanilid in quantity at this writing is 25 cents a pound. Another probable reason for replacing acetanilid is because acetphenetidn is supposed to have a less deleterious effect on the human system than the former, but at present this is an open question. No one has thus far ventured to give this as an excuse for using antipyrin, because it is a well-known fact that the latter is the most dangerous of these three medicinal agents. Two other potent factors, however, should be considered in this connection. These are: First, the deleterious effects of neither acetphenetidn nor antipyrin have been given any publicity and the public, therefore, has little knowledge of the meaning of the words acetphenetidn and antipyrin should their presence be declared on the label, second, it was expected that both of these chemicals could be used indiscriminately in medicines without the necessity of declaring their presence on the label. Acetphenetidn however, according to the rules and regulations made under the Food and Drugs Act, must be set forth on the label.

The use of harmful preservatives in food products is forbidden. The exact status of the harmful nature of certain preservatives is not definitely settled at present. Among the most conspicuous preservatives used during recent years are the synthetic chemicals known as salicylic acid and benzoic acid and their salts. The experimental results obtained in the Bureau of Chemistry in connection with salicylic acid and salicylates have just been published in Bulletin 84 part 2 from which part of the general conclusions are herewith quoted.

There has been a general consensus of opinion among scientific men, including the medical profession, that salicylic acid and its compounds are very harmful substances, and the prejudice against this particular form of preservative is perhaps greater than against any other material used for preserving foods. This is due not only to the belief in the injurious character of salicylic acid, but perhaps is especially due to the fact that it is in the past been so generally used as an antiseptic. That salicylic acid should be singled out especially for condemnation among preservatives does not seem to be justified by the data which are presented and discussed in this bulletin. That it is a harmful substance, however, seems to be well established by the data taken as a whole, but it appears to be a harmful substance of less virulence than has been generally supposed. The addition of salicylic acid and salicylates to foods is, therefore, a process which is reprehensible in every respect, and leads to injury to the consumer, which, though in many cases not easily measured, must finally be productive of great harm.

Benzoic acid and the benzoates are by many considered less harmful than the salicylates. Whether or not this is correct remains to be established by future experiments and observations. This much, however, is certain, that whenever it is possible, and usually it is, food products should be prepared without the use of any questionable preservative.

Saccharin is generally employed as a sweetening agent and its use is largely of a deceptive character because the consumer usually believes when he is eating a food product sweetened with this chemical that the sweetening is due to some form of sugar. The use of saccharin as a sweetening agent is not only common in food products, but also in medical remedies. Saccharin is a most valuable agent in certain diseased conditions, but this does not justify its indiscriminate use. Inasmuch as deceptions and misrepresentations of all kinds are prohibited under the act, the presence of this chemical should be declared on the label.

The synthetic production of vanillin undoubtedly was one of the greatest scientific achievements and triumphs of chemistry. Vanillin is a very valuable commodity. It is claimed by many that flavoring preparations made with vanillin as a basis possess distinct advantages over extracts made from the vanilla bean. There is no question whatever but that vanillin possesses certain merits not inherent in the vanilla bean, and it seems rather incomprehensible why manufacturers do not take advantage of this fact and sell vanillin preparations on their merits. Let not vanillin in disguise deprive extract of vanilla of its time-honored reputation.

TINCTURE OF STROPHANTHUS

R. A. HATCHER, Ph.D., M.D.

Assistant Professor of Pharmacology, Cornell University Medical College
Member of the Council on Pharmacology and Chemistry
of the American Medical Association

NEW YORK CITY

Strophanthus has not rivaled digitalis in the extent of its use, except, perhaps, for a short time after the former was brought into prominence by Fraser. This is somewhat remarkable in view of the fact that numerous investigators have found that the action of strophanthus presents certain advantages over that of digitalis; thus, strophanthus and to a greater extent its active principle, strophanthin, act much more promptly than digitalis or digitoxin. Fraenkel found that the action of a single effective dose of digitoxin was delayed for many hours beyond that of a corresponding dose of strophanthin, and while he was unable to induce

slowing of the cat's heart from a single non-toxic dose of digitoxin, a single non-toxic dose of strophanthin promptly proved effective. Strophanthus produces much less vasoconstriction in the splanchnic area than digitoxin does, and while this is a disadvantage in shock, it is often desirable in producing diuresis, since the constriction of the vessels in the kidney by digitoxin may seriously interfere with the diuretic action.

Gottlieb and Magnus working with the isolated cat's heart, found that strophanthus caused practically no constriction of the coronary vessels in contrast with the action of digitoxin, with which the constriction was found to be so marked at times as to completely mask the other actions on the heart. This must be of considerable importance when hypertrophy of the heart is the object sought, since these investigators have found that the actions of the two drugs on the heart are otherwise practically alike. According to Fraenkel, cumulative effects are not nearly so readily induced with strophanthin as with digitoxin.

Strophanthin further possesses the following advantages over digitoxin. It is much more soluble in water, it is not irritant, and, therefore, may be injected hypodermically; it is much more active and not nearly so expensive as digitoxin.

R. Heinz states that the therapeutic effects of strophanthus are the same as those of digitalis, while strophanthus exhibits much less of the disagreeable side effects.

With these evidences of its advantages it is well to inquire why strophanthus has not come into more general use, at least in suitable cases. For I am not prepared to say that it should be used to the exclusion of the better-known drug.

Heinz states that strophanthus fell into disfavor in Germany soon after its introduction owing to the fact that a number of species of widely varying activity were employed. Some samples of the tincture were found to be but one-sixtieth as active as others. Under the circumstances it was inevitable that the drug should fall into disrepute. While I am not aware that any comparative tests were made of the strength of tinctures found in commerce in this country about the time of the introduction of the drug, it is extremely probable that variability existed here to the same extent as that observed in Germany, and naturally with the same inevitable result.

Of late years strophanthus has been used with satisfactory results in Holland, Belgium, and France, and that alone proves that a fair degree of uniformity in the preparation now obtains in those countries. In order to determine whether a similar degree of uniformity now prevails here, a number of samples of tincture of strophanthus were bought from as many drug stores on the east side in New York City and compared with tinctures carefully prepared by myself from the best obtainable seed, as well as with specimens prepared from samples of seed which had been on hand for different periods of time.

Owing to the extreme difficulty in making chemical tests of these preparations the physiologic test recently advocated by Fraenkel was employed. This consists in determining the amount necessary to produce a complete standstill of the ventricle of the frog's heart. The test is made accurate and more exact on frogs, and those of

experiments The degree of potency is usually shown rather strikingly in mammals by the rapidity of onset and the intensity of vomiting, as well as by the depression seen after varying doses. That this is an index of the therapeutic activity is proved by the fact that pure strophanthin, which has been much used in pharmacologic investigations, presents no preceptible difference in its action.

While the bare figures given in the tables do not convey nearly so accurate an idea of the relative degree of potency of the several samples as one gets by actual observation of the experiment, they afford sufficient proof that we are not dealing with any great variation in strength.

In this connection it should be borne in mind that the tincture of strophanthus, U S P, VIII, is of 10 per cent strength, whereas that of the previous edition was but half as strong, and the physician should assure himself that the patient gets the stronger preparation.

For the purpose of the experiment the several tinctures were diluted so that one c.c. of the dilution represented one milligram of the seed, this was injected into the ventral lymph space in frogs and hypodermically in mammals. While exactly uniform results were not obtained, as might be expected, the experiments showed a fair degree of uniformity not only in the various specimens bought in the open market and those freshly prepared, but a tincture made from seed which had been in this laboratory for at least sixteen years was found to be as potent as the standard. One specimen of tincture bought from a drug store on the west side and kept in this laboratory for eighteen months showed the same degree of potency as the freshly-made preparations.

The various samples of tincture were obtained as follows:

- No I Made in this laboratory from powdered seed obtained from Gilpin Langdon & Co., in the spring of 1905
- No III Made in this laboratory from seed which had been in the laboratory for more than sixteen years
- No IV Made in this laboratory from seed obtained from Gilpin, ngdon & Co. in September 1906
- No VI Bought at retail labeled Squibbs
- No VII Bought at retail labeled Parke, Davis & Co. U S P, 90
- No VIII Bought at retail said to have been made from Gilpin Langdon & Co's ground drug
- No IX Bought at retail labeled Sharpe & Dohme Age unknown
- No \ Made in this laboratory from Gilpin Langdon & Co's ground drug. Obtained in September 1906
- No XI Bought at retail, labeled Parke Davis & Co. U S P 1890
- No XII Bought at retail labeled Squibbs.
- Nos 11 and 5 were not used in this series of experiments

TABLE 1—EXPERIMENTS ON FROGS

Specimen No	Dose—Equivalent of 10 per cent. tincture per 100 grms. per frog	Result in One Hour
I	0.000 c.c.	Ventricular standstill (in 2 out of 3)
III	0.004 c.c.	Ventricular standstill
IV*	0.000 c.c.	Ventricular standstill
VII	0.000 c.c.	Inconclusive (only three experiments)
VIII	0.01 c.c.	Ventricular systolic standstill (Invariably)
IX.	0.000 c.c.	Ventricular systolic standstill about one-half the experiments

* This amount was found to be the minimum quantity of this specimen required in a large number of experiments to produce ventricular systolic standstill fairly regularly then the same amount of other specimens was used for comparison.

To facilitate comparison of toxicity Table 3 is compiled from Table 2 without taking into account cumulative action which is not very important at this time, except with Specimen VI

The first five preliminary tests on cats were made to determine whether any degree of uniformity of action

might be expected. The results show a much closer agreement than had been anticipated, but it was seen that with such massive doses, killing so quickly, the interval before death would be more dependent on accidents of absorption than would be the case when some hours must elapse.

As vomiting is such a common symptom, not only

TABLE 2—EXPERIMENTS ON CATS AND DOGS *

Date	Animal No	Specimen No	Dose—equivalent of 10 per cent. tincture in c.c. per Kg	Result
CATS				
	1	X	0.17	Emesis in 20 min death in 43 min
	2	VI	0.17	Emesis in 15 min. death in 29 min
	3	VIII	0.17	Emesis in 18 min., death in 60 min
	4	VII	0.17	Emesis in 15 min. death in 44 min
	5	IV	0.1	Emesis in 17 min, death in 86 min
Dec. 19	7	I	0.0125	Emesis in 68 min, many times repeated.
Jan. 23	7	I	0.01	Emesis in 2½ hours, but once.
Jan. 24	7	I	0.0075	Emesis in 10 min, many times repeated
Jan. 28	7	XI	0.0125	Emesis in 47 min. many times.
Dec. 19	7a	I	0.0125	No effect
Dec. 21	7a	I	0.025	Emesis in 31 min many times.
Dec. 22	7a	I	0.05	Emesis in 7 min death in 36 min
Jan. 25	9	VI	0.0125	Emesis in 2 hours
Jan. 28	9	VIII	0.0125	Emesis in 1 hour, 50 min
Feb. 1	9	VIII	0.04	Emesis in 33 min death in 2 hours
Jan. 28	10	III	0.0125	No effect.
Jan. 30	10	III	0.0125	No effect.
Feb. 1	10	VI	0.017	Emesis in 56 min
Feb. 2	10	III	0.017	Emesis in 21 min (slight cumulative action)
	10	III	0.023	
	Total in	half hour	0.04	Death in 4 hours
Jan. 28	11	VII	0.0125	No effect
Jan. 30	11	VII	0.0125	No effect
Jan. 31	11	VII	0.017	No effect.
Feb. 2	11	VII	0.017	Emesis in 53 min
	11	VII	0.023	
	Total in	one hour	0.04	Emesis with great depression nearly fatal.
Feb. 4	11	VII	0.04	Death in 83 min. (some cumulative action)
Jan. 30	12	IX.	0.125	No effect.
Jan. 31	12	IX	0.017	No effect.
Feb. 1	12	VI	0.017	Emesis in 54 min but once
Feb. 2	12	IX	0.017	Emesis in 12 min
	12	IX	0.023	
	Total in	half hour	0.04	Emesis frequently repeated, nearly fatal
Feb. 4	12	IX.	0.04	Emesis in 8 min death in 68 min
Jan. 30	13	III	0.04	Emesis in 37 min. great depression next day
Jan. 31	13	III	0.04	Emesis in 17 min death in 60 min
Feb. 8	14	VI	0.04	No effect
Feb. 9	14	VI	0.04	No emesis, death in 44 min.
Feb. 8	15	VII	0.04	Emesis in 74 min death in about 36 hours.
Feb. 8	16	XI	0.04	Emesis in 20 min death in 3 hours 15 min
Feb. 11	17	VII	0.04	Emesis in 18 min death in 62 min.
DOGS				
	1	I	0.04	Emesis many times repeated nearly fatal
	2	IX.	0.04	Emesis in 70 min death in 3 hours 5 min.

* While the rapidity of action in animals 1 to 5 affords a means of fairly accurate comparison it was thought preferable to employ amounts just sufficient to produce vomiting and others about the minimum fatal dose.

after the tincture of strophanthus, but also after pure strophanthin, it was thought that this symptom might be used as an index of potency. While this is true to a certain extent, the resistance to the action on the vomiting center is more variable than it is to the action on the heart, and it was, therefore, considered better to determine the amount necessary to produce systolic stand-stills, which is, of course, promptly followed by death, unlike the case in frogs in which there may be no visible outward symptoms for some hours after the heart ceases to beat.

TABLE 3

Specimen	Dose	Animal	Result
I.	0.04	Dog	Emesis and great depression almost fatal
III.	0.04	Cat.	Death in 4 hours.
VI	0.04	Cat.	No effect (tolerance)
VI	0.04	Cat.	Death in 44 min (total in 24 hours of 0.08)
VII	0.04	Cat.	Death in about 36 hours
VII.	0.04	Cat.	Emesis with great depression
VII	0.04	Cat.	Death in 83 min (second dose in 48 hours)
VIII.	0.04	Cat.	Death in 2 hours
IX.	0.04	Cat.	Great depression (0.017 given 24 hours previously)
IX	0.04	Cat.	Death in 08 min (dose given 48 hours after preceding)
IX.	0.04	Dog	Death in 3 hours 5 min
XI	0.04	Cat.	Death in 3 hours 15 min.
XII	0.04	Cat.	Death in 62 min

One-eightieth of a c.c. per Kg. of the 10 per cent. tincture was the smallest initial dose which was found to produce vomiting, though less than a hundred and twenty-fifth of a c.c. was effective twenty-four hours after a somewhat larger dose. On the other hand, cat 14 did not vomit after ten times this amount given in the course of two days, though death resulted speedily after the second dose.

I wish to reiterate that the object of these experiments was not to show any exact uniformity in the action tincture of strophanthus from various sources, for this is manifestly impossible, but to prove that we have a vastly more uniform product than in the case of the preparation of digitalis.

It may be remarked, wholly parenthetically, that these results do not confirm the charges which it has become the fashion to make in regard to the unreliability of the pharmacists of New York. The various specimens were not obtained from the better class of stores but in most cases from those in the poorer quarters.

In conclusion it may be stated positively that there is no difficulty in obtaining tincture of strophanthus in the open market of quite as nearly uniform potency as obtains in the case of tinctures of other drugs which are not standardized, and that the seeds do not undergo deterioration on being kept for several years, possessing in this respect a great advantage over digitalis leaves, which deteriorate rapidly despite care on the part of the pharmacist. Digitalis continues to be of very variable strength, not only for the reason just stated, but owing to want of uniformity in the time of collection, methods of drying and source even when the official requirements are met. It should be remembered also that the strength of the infusion of digitalis varies greatly with the manner of preparing it, an infusion made from the powdered leaf much more nearly representing the full potency than one made from the leaf which has been merely broken up in the mortar, as is frequently the case.

The Duty of the Hospital.—The medical institution is under obligation to administer its charity wisely, to aid in medical education, and to protect its staff from imposition.—E. B. Young, M.D., in the *Bull. of Am. Acad. of Med.*

Clinical Notes

MEASURED QUANTITIES OF STERILE FLUIDS

PRELIMINARY COMMUNICATION

A. PARKER HITCHENS, M.D.

GLENOLDEN, PA.

Almost all the devices in use at the present time for filling tubes or bottles with definite quantities of fluid depend for the *vis a tergo* on the gravity of the fluid column. When wishing to depart from this simple method, as is sometimes desirable or necessary, one is confronted with several difficulties. To overcome these, rather expensive and complicated appliances are necessary, the manipulation of which requires considerable time. The pump I have devised was suggested by the respirator sometimes used by chemists when working with dangerous gases.

Aseptic pump for transferring measured quantities of sterile fluids.

The apparatus consists of two glass valves, a graduated burette, and a piston syringe. Each valve, A A', consists of a capsule into which is fitted a very carefully ground stopper, B B'. These stoppers are weighted with mercury so that they will sink into place quickly and accurately. These valves are connected with the graduated burette as shown in the diagram. When traction is made on the piston D, the valve B is lifted and the fluid passes into the burette C. When the suction ceases the valve settles and prevents the least regurgitation. The piston D is now pushed into the syringe, pressure in this direction closes the valve B more tightly and opens the valve B' which allows the fluid to pass out at the shielded delivery tube E.

The pump is easily sterilized by allowing an anti-septic to stand in it for the proper length of time. This anti-septic may be washed out with either sterile water or salt solution. By the use of a spring or weight and stop one may easily arrange so that the burette will be filled automatically.

SARCOMA OF THE TESTICLE

A. L. WOLBARST, M.D.

Attending Genito-Urinary Surgeon, Beth Israel Hospital Dispensary
NEW YORK CITY

Tumors of the testicle are fairly often seen in genito-urinary practice, but their diagnosis is not always a simple matter. Especially is this true of malignant growths, because of their close clinical resemblance to tuberculous and syphilitic deposits. Hence the interest in the unusual case herein reported.

When a man presents himself with an abnormally large testicle or a large mass in the scrotum, we have to think of numerous conditions that might be causative factors, and as a matter of clinical interest I have enumerated the following formidable list of possible conditions that must be thought of: Tuberculosis, syphilis, malignant and benign growths, inflammatory and non-inflammatory orchitis and epididymitis, hydrocele, varicocele, hematocele, spermatocele, cystic growths, torsion of the testicle, intestinal hernia, contusions and wounds of the testicle, hemorrhagic infarcts of the testis, fungus, and general hypertrophy of the testicle.

Most of these conditions are easily diagnosed. Thus, varicocele is easily distinguished by the knotted and tortuous veins of the spermatic or pampiniform plexus which surround the spermatic cord. In the average case this condition can not be mistaken for anything else. In extreme cases, however, the loose mass of veins and their surrounding tissues constitute a well-defined tumor which must be differentiated from other tumors, it is soft and mushy to the touch and gives to the finger a characteristic sensation that has been described as resembling a bundle of worms in a bag. The scrotum on the affected side is dragged down and elongated to a greater or less degree by this mass of veins and often assumes a purplish color.

Hydrocele is often difficult to diagnose, especially as against the presence of hernia. Unless tension be extreme, hydrocele is usually painless, and is thus distinguishable at once from inflammatory conditions. There are no constitutional symptoms. Its smooth, pear-shaped surface, absence of glandular involvement, and the normal testicle and epididymis when they can be felt, differentiate it from tuberculosis, cancer and cystic disease. Fluctuation, irreducibility and in most cases translucency, as determined by the "light test," differentiate it from hernia, and, as a final measure, aspiration of its clear serous fluid removes all doubt as to the diagnosis. Bloody fluid removed by the aspirating needle indicates the presence of an hematocele, unless, perchance the testicle has been wounded in the act of aspiration. It should be remembered, however, that neither hydrocele nor hematocele precludes the presence of a malignant growth, on the contrary, the latter is often thus accompanied.

Acute inflammation of the epididymis and testis proper is easily distinguished from malignant growths. The acute onset, pain, tenderness, rise of temperature and other evidences of acute inflammation make the diagnosis simple enough, especially as these symptoms are usually associated with a history of gonorrhea or trauma. In old men with prostatic hypertrophy, the possibility of the development of acute orchitis or epididymitis without apparent cause should always be borne in mind. At the same time we should not forget the comparative frequency of recurrent attacks of epididymitis and orchitis months and even years after the predisposing gonorrhea has been forgotten by the patient.

In obscure cases of inflammatory swelling of the testicle the presence of parotitis and other infectious diseases should be determined.

Wounds, contusions and torsion of the testicle should not be mistaken for anything else, and similarly with that non-pathologic form of testicular hypertrophy which is often found as a compensatory physiologic condition, after one organ has been removed by disease or operation. Sometimes a condition is met with in which one gland is abnormally large while the other is correspondingly small, neither condition is necessarily pathologic.

Another fairly common tumor of the testicle is a collection of fluid either in the tunica vaginalis testis, or, as is more often the case, in a cyst in and about the epididymis. This condition is known as spermatocele, or encysted hydrocele of the testicle. The fluid is a milky serum containing the spermatic elements, principally spermatozoa. These cysts may be small or large, they are usually found separating the epididymis from the testicle, and form a more or less irregular, pear-shaped, fluctuating tumor. Sometimes more than one of these tumors will be noted. When these cysts rupture into the tunica vaginalis, as they often do, they constitute the so-called spermatic hydrocele, which, in essence, is similar to the common form of hydrocele, except that the fluid contains spermatozoa.

These spermatic cysts should not be confused with the less frequent cystic growths of the testicle proper—teratoma, benign and malignant cystic disease. Clinically it is well-nigh impossible to differentiate one type from another.

Patient—J. S., aged 36, Russian, married, tailor by occupation, presented himself on Jan. 13, 1906, with a large mass in the left side of the scrotum.

History—Family and personal history negative as to gonorrhea, cancer, tuberculosis and syphilis. Patient is the father of five healthy children, the youngest an infant a few days old, and of good health. The testicular swelling, though considerably smaller than at the time of examination, had been present for about ten or eleven years, but only during the past ten months had it grown to the present great size. There was little or no pain, except for the dragging sensation caused by the weight of the mass, pulling continuously on the cord and scrotum.

Examination—From apex to base the mass was 7 inches long, $4\frac{1}{2}$ inches in width and 13 inches in circumference at its widest part. To the touch it was hard and tense, and in the upper portion fluctuation could be determined. The testicle proper and the epididymis could not be distinguished. There was no elevation of temperature, pulse was normal, appetite and general health good. Heart, lungs and abdominal viscera were likewise normal. There was no glandular enlargement anywhere in the body. The patient believed that during the last few months he might have lost a few pounds in weight. The urine was clear and normal in all respects, the prostate was normal in shape, size and consistency. The seminal vesicles could not be felt. Bacteriologic examination of the urine for tubercle bacilli was negative, the secretion from the massaged prostate revealed no gonococci nor tubercle bacilli.

Subsequent History—Three days after the first visit I inserted a trocar and withdrew about three ounces of clear serum, which was also examined bacteriologically for tubercle bacilli with negative result. After the fluid was withdrawn the testicle and epididymis were easily distinguished. The former was about three times its normal size, hard and stony to the touch but not tender, except on excessive pressure. The epididymis was at least four times its usual thickness, hard, nodular and of serpentine outline. It was separated from the testicle proper by a distinct deep groove, but it did not present the so-called "clam shape" of Keyes.

Diagnosis—Other conditions having been eliminated, there

remained to consider tuberculosis, syphilis and malignant disease. The absence of tubercle bacilli in the hydrocele fluid and in the prostatic secretion, the absence of tubercular involvement of the prostate and seminal vesicles as well as the thoracic and visceral organs was considered strong enough evidence to eliminate tuberculosis. For various reasons the tuberculin test could not at that time be made.

Treatment—The patient was put on fairly large increasing doses of iodid of potassium (up to 100 grains three times daily), in addition to which he received two injections of salicylate of mercury (each containing 15 drops of a 10 per cent solution), the iodid was continued for about three weeks, but the injections were stopped because of the pain which followed. As a substitute for the salicylate he was given half a dozen injections of a 1 per cent solution of mercuric iodid in oil, which were found to be quite painless and well tolerated. After four weeks of this treatment it was seen that the mass had diminished slightly in size, but not sufficiently so to justify the belief that it would respond further. Within a few days after the first aspiration the fluid returned and was again withdrawn. This time it came out dark and bloody in contrast to the clear fluid withdrawn at the first tapping. This operation was repeated at intervals of several weeks, and each time the same bloody fluid was withdrawn.

Operation—On May 18 I removed the testicle and epididymis *en masse* and the patient made an uneventful and quick recovery. Dr. Jeffries, at the Polyclinic Hospital, made an examination of the tumor and reported it to have been a round celled sarcoma, showing cystic degeneration. On September 10, three months after the operation, the patient, who had been under observation all this time, complained of a dull, heavy feeling in the upper gastric region. On examination it was found that the left lobe of the liver was considerably enlarged and was exerting pressure on the pyloric end of the stomach. The liver grew at an enormously rapid rate, the gastric symptoms increased and the man lost flesh and strength rapidly. He was again put on antisyphilitic treatment with the hope of effecting some relief, but it was of no avail. He was unable to continue at his work and returned to his birthplace in Russia. I have not heard from him since.

Apart from the difficulty in making a diagnosis without operation, this case presents these interesting features:

- 1 The growth was present in a dormant stage for about ten years.
- 2 For some unknown reason, the tumor took on a sudden growth, very rapid in its nature, and reached its maximum size in the comparatively short period of ten months.
- 3 Careful search revealed the absence of metastatic deposits where such deposits might have been expected.
- 4 The patient's general health did not apparently suffer at any time before removal of the tumor.
- 5 The antisyphilitic treatment did have a slight ephemeral effect on the mass.
- 6 Within three months after operation the liver showed metastatic deposits of an extremely malignant type, accompanied by great deterioration in general health for the first time.

ADDENDA In a communication received March 24 1907 from Dr. Herman Lorber, just returned from Vienna, the doctor writes: "Perhaps you will be interested in a patient of yours whom I saw in the Krankenhaus in Vienna. It was the patient with sarcoma of the testicle whom you showed at the medical meeting last year. Professor von Noorden showed the patient. He has lost considerable flesh and strength, the liver is enlarged considerably but the spleen even more so, and very hard. The diagnosis of sarcoma was of course confirmed."

COMPLETE RESTORATION OF FUNCTION OF TORN SPHINCTER ANI MUSCLE AFTER 23 YEARS OF ATROPHY AND DISUSE

ROBERT H. V. DAWBARN, M.D.
NEW YORK CITY

The accusation is sometimes made that surgeons who have had the good luck to score an exceptional success are apt to rush into print and report it to the profession without waiting a reasonable time in which to ascertain whether or not the cure can properly be classed as a permanent one. However I think we may consider the following patient definitely and permanently cured, whose case—possibly unique in point of time between her sphincteric loss and its restoration—I now publish for the first time six years after the operation. My library search has not been thorough, and reports from those who have completely cured patients longer afflicted would be of interest.

The patient, a lady in the family of a physician in this city, states that she can now control, even during an occasional diarrhea, her bowel movements as perfectly

Fig. 1—A the upper shaded part represents the raw surface of rear wall and sides of vagina from which the flap B the lower shaded part hangs down. The arched broken line between A and B indicates the upper limit of the rectal and vaginal tear. One must not dissect closely enough to this to threaten the blood supply of the flap. C and C' are the exposed ends of the sphincter ani. These are brought together. The apposition of the raw surfaces above will be helped by using as a first step the suture the ends of which L and E are to be tied together.

as ever before the tear. If this muscle, during such a great period of absolute disuse and atrophy, can so retain the capability of restoration of function after the necessary operation it would seem that never in a life time is this power hopelessly lost and that it would never be unreasonable to hope that the power of any or all of the sphincters lost through injury might be regained.

The following are briefly the central facts of the case. Twenty-three years and nine days before the operation the patient was torn so badly during an instrumental birth that the tear, as shown in the diagram, extended half way up the rectum to the same level as the tear in the vagina. In consequence one opened and during all the years

of her bowel movements. Almost wholly disbarred from going into society, her misery during this period can readily be imagined.

On November 27, 1900, I operated, assisted by Drs Charlton Wallace and J W D Maury, her family physician, Dr Stuart Close being present. The technic employed was one which in its simplicity and application seems hard to improve on. It was devised by Dr Rustine of Knoxville, Tenn., more than twelve years ago and its technic was published by him some years afterward in the *American Journal of Obstetrics and Diseases of Women*. The details, accompanied by a rough sketch, which may serve better than words to make clear one or two steps, are as follows. The rectum being empty and cleansed, is packed with gauze. A horseshoe-shaped flap of mucous membrane, with its toe upward, is next outlined. The incision for this begins on either side of the vagina at the ends of the torn and retracted sphincter ani. The cut ascends on either side and meets at the toe, placed, in a case as bad as this, just as high as possible behind the cervix uteri—almost touching the cervix—so as to waste no length of flap that it is possible to secure. With a tear only dividing the sphincter, and not the rectum, obviously the horseshoe cut need not ascend so high.

The apron of the flap thus turned down will have its sound, i. e., its mucous membrane surface toward the feces and its raw surface forward. It will be dissected down as far as the upper end of the tear permits. If of proper length its lower or free ends should now hang as low as the anal level behind it. Any excess of length of this apron is a protection, for the time, to the dissected flesh in front against accidental infection, and if it should not finally shrivel it can be snipped away.

Search is next made for the torn sphincter, the ends of which must be freshened and then brought into mutual apposition by means of tanned or chromicized catgut. The sphincter muscle, even in this case, could still be plainly recognized. By dissecting down and lengthening the horseshoe ends as needed, tissue is at length reached which when seized and pulled on by the forceps can be felt to draw the sphincter on either end. Before apposing these ends we should insert and tighten the continuous suture shown as E and E' in the accompanying sketch. This helps to prevent any "dead space." The curved needle is inserted and brought out but four times in passing this stitch. Following the union of the sphincter the surgeon will probably perform the customary operation for torn perineum.

Before concluding, a moderate section of the sphincter at the rear anal margin should be made (in a case recently torn) to weaken it temporarily—for protection against the tearing out of the important stitches uniting its ends. Perhaps I need not say that in the case under discussion, after twenty-three years of disuse, it was thought unnecessary to weaken the sphincter further in this way. When this is done no stitch is taken, a clot fills the tiny opening made by the slender blade. The bowels are moved the second day and each day thereafter. Electricity and strychnin are of value in aiding the sphincter to recover its function.

I would refer those especially interested to the article by Dr Charles G Child, Jr., of this city, in the *Journal of Obstetrics and Gynecology of the British Empire*, July to December, 1905. It will be found that in a few particulars my operation differs from that of Dr Rustine—the principle, however, is his, as also should be the entire credit of this, one of the very few operations which seem to me perfect in technic.

APPENDECTOMY DURING HERNIOTOMY

JOHN A. HAWKINS, M.D.

Professor of Rectal Diseases in the Medical Department of the Western University of Pennsylvania. Rectal Surgeon to St. Francis Hospital
PITTSBURG, PA.

The article by Dr John A Wyeth, in *THE JOURNAL*, Nov 24, 1906, reminded me of two patients on whom I recently operated.

The first patient, a man of 67, had suffered with a large inguinal hernia for many years. On opening the sac I found that it contained the cecum, the adherent appendix and part of the ileum. The appendix, though not inflamed, was removed, and the abdomen closed by the imbrication method of Fowler. Recovery was uneventful.

The second case was that of a woman of 62, who suffered from an inflamed bubonocoele. The sac contained a structure of whose identity I was not altogether certain until I had examined it closely, but which proved to be the appendix. The constricted ring was incised and the hernia repaired by the Bassini method, the appendix being removed in the usual way. There was nothing unusual about the recovery. The appendix was 10 cm in length, 12 mm in diameter at the distal end and 4 mm at its attachment, being club shaped.

A CASE OF INFECTION BY STRONGYLOIDES INTESTINALIS*

J N HALL, M.D.

Visiting Physician to the Denver City and County Hospital
DENVER

This parasite, associated with Cochín-China diarrhea, has been reported so rarely in the United States that the following case should be recorded. The exact relationship to tropical diarrheas seems not definitely established.

Patient—A Japanese ship's cook, aged 40, was admitted to my service in the Denver City and County Hospital, Oct 18, 1906.

History—We learned that he had visited many ports in Asia and other parts of the world, had been in America seven years, in Colorado three years. He had been sick for ten weeks, although below par for three or four months. He had a slight cough, had probably lost 20 or 30 pounds in weight, and was moderately anemic. He had five to eight stools in the twenty four hours, mushy in consistence, foul smelling and of clay, slate or dark green color. No blood nor mucus. He complained of constant pain in the abdomen, and in the rectum on defecation. He vomited a few times, especially after eating sweet food.

Examination—Physical examination of the chest and abdomen was negative. The urine was acid, sp gr 1030, a trace of albumin, no sugar, no bile, indican increased. A few small and narrow hyaline and granular casts, occasional blood cells and leucocytes. The examination of the sputum was negative. The blood, two weeks before death, showed Hemoglobin (Tallquist), 65 per cent, red cells, 3,200,000, white cells, 4,400. Moderate polikilocytosis and no megaloblasts nor normoblasts were found. A differential count of white cells showed polynuclear neutrophiles, 51.5 per cent, lymphocytes, large and small, 47 per cent., eosinophiles, 05 per cent. The absence of eosinophilia is to be noted.

Suspecting amebic dysentery, I asked Dr B B Blotz, in charge of the laboratory, to examine the stools. His report is as follows:

"Larvæ of the *Strongyloides intestinalis* were found in great numbers. At least fifteen examinations were made and the parasite was present in each. An attempt was made to obtain the adult by incubating the larvæ for seventy two hours at

* Reported with exhibition of specimens to the Denver City and County Medical Society No 6 1906

37 38 C This was unsuccessful At one examination a parasite was found having the same characteristics as the larvæ, but three times as long The ova of the parasite were not discovered Red blood cells and Charcot Leyden crystals were found at various times In the last two or three stools examined there were numerous black crystals, rhombic, quadrangular and needle shaped, probably of hematogenous origin These crystals were also found in the vomitus A search was made for the ova of the ankylostoma duodenale, said to be often found in association with this parasite, but they were not discovered, nor could other ova be found During the last few days the patient vomited several times in each twenty four hours, and the parasites were abundant in the vomitus"

In every specimen of the fresh stools, mounted with water, under a power of 50 diameters, could be seen from five to thirty of the larvæ in active motion After an hour or two, most of them became immobile, but could be resuscitated by adding more water and warming the slide slightly The patient was fed on a liquid diet and given thymol in a dose of 15 grains three times a day At the suggestion of Dr Ralph Taylor, who had seen the parasite in his Philippine experience, 3 grains of santonin were added later Although the parasites lost their activity, so that but one or two sluggish ones could be found in a field, with perhaps a dozen dead ones, the patient steadily lost ground, and died on Nov 17, 1906 No autopsy could be obtained.

RESPIRATION VALVES

C C GUTHRIE, M.D.

Professor of Physiology and Pharmacology, Washington University
Medical School
ST LOUIS

The valves shown in the accompanying drawing were designed primarily for use in preventing the waste of volatile anesthetics that commonly occurs in mammalian experiments when a Wolff's bottle is used in connection with a trachea tube and for simplifying the measurement of expired air in such experiments Construction of plated brass with valve discs of aluminum, or of aluminum throughout, is satisfactory An average of results from a test made on an 8 Kg dog during a period of four hours is given below The valves were not observed to stick or miss catching throughout the experiment

1 Animal with tube in trachea breathing through a Wolff's bottle arrangement Valves connected on the far side of the

Valve mechanism for laboratory experiments with respiration IA inspired air EA expired air SC, spirometer connection BC, bottle connection TC trachea connection Sp valve stop D valve disc St, valve seat

bottle in order to measure the volume of expired air Volume of air measured by conveying it through a tube from the side branch to a spirometer

2 Same arrangement as in 1, only the valves were inserted between the dog and bottle so that the expired air did not pass back through the bottle as in the first case

RESULTS

1 Amount of ether used per L of air 0.83 c.c.

2 Amount of ether used per L of air, 0.42 c.c.

The average volume of expired air per minute was 3866 c.c. For simplicity calling it 4 L, the amount of ether used per hour in 1 was 199.2 c.c., and in 2, 100.8 c.c.

The use of the valves also prevents contamination of the anesthetic contained in the bottle by condensation of moisture from the animal's breath

AN IMPROVED BEDSIDE CHARTHOLDER FOR HOSPITAL USE

J D SINGLEY, A.M., M.D.

Surgeon to the Pittsburg Hospital
PITTSBURG, PA

In this chartholder the back is a rigid light enameled metal plate The clamp or clip is of heavy wire and has two contact points, but instead of relying on metal or small rubber tips at the contact points, as in those on the market, two rings come in contact with the back Two upright pins about one inch high are set into the back over which the rings drop when the spring of the clamp is released The record sheets, after padding, are perforated, at a very slight cost, by the printer at the proper place for the pins

With such a holder the record sheets can only be released by exerting sufficient pressure to raise the ring of the clamp clear of the pin and lifting the sheets off the pin No adjustment is required to keep the various sheets in alignment while the proper sequence of the sheets remains as originally placed

812 North Highland Avenue

Malaria and Tuberculosis—P Cracieux has been investigating conditions in tropical Africa and Mexico, he found malarial antecedents in 70 per cent of the natives affected with tuberculosis He believes that this malarial infection paves the way for tuberculosis later and that it is absurd to claim that the native races are peculiarly predisposed to tuberculosis They have only unusual opportunities for malarial infection, and this is the tuberculosis His article opens the

"RUBBER TUBE PERCUSSION"

ARNOLD C. KLEBS, M.D.
CHICAGO

Dr F. M. Pottenger has recently recommended¹ immediate percussion with a rubber tube, which, he believes, is a "method of greater precision" and possessing "superior advantages over methods in common use."

The usefulness of all methods of percussion depends, of course, largely on the individual who uses them, good as well as bad results can be obtained with almost any method. But a new clinical method must have both intrinsic as well as heuristic value, otherwise it constitutes merely an encumbrance to an already confusingly large diagnostic armamentarium.

If we analyze Pottenger's announcement we find that he really does not describe a method, but merely advocates the use of a rubber tube instead of the hammer. One naturally surmises, since nothing to the contrary is stated clearly, that the tube is to be used as one ordinarily uses the hammer or the finger, i. e., with a rebounding blow. We find some intimation, however, that here, unlike ordinary percussion, in which the percussor is retired as rapidly as possible so as not to deaden the vibration, the instrument is left where it struck. It would have helped toward the understanding of the "new method" if this and other points had been made clearer. The author also does not enlighten us on his contention that "with the use of the rubber tubing there is no noticeable thoracic resonance." Since the whole value of the "old method" is based primarily on the acoustic appreciation of modified thoracic resonance it would be rather interesting to know the author's scientific evidence which induces him to believe that with his tube he is able to produce isolated sounds emanating from the underlying organs. He can not well imagine that the mere contact of a flexible, resilient tube can prevent this to a noticeable extent, and so give him "the simple tone of the underlying tissue." Contrary to his assumption, which also is in contradiction to all accepted theories of percussion and acoustics, I should think that he must get this "tone," plus that of the thoracic wall and plus that of the tubing itself. Thus far we have tried to minimize the disturbing by-sounds by firmly adapting our finger or plessimeter to the chest wall.

But the author is evidently out for results, not for theories, and so I have tried the "new method," adhering faithfully to his directions so far as they go. I found that the tube when struck, indeed, emits a sound, but that the strength and quality of this sound is chiefly influenced by the length of the portion of the tube striking the chest (the length varying between $1\frac{1}{2}$ and $2\frac{1}{2}$ inches), by the length of tubing held in the hand and also by the pressure exerted on the tubing by the hand. To a certain extent, of course, this sound inherent to the swinging tube is modified by the vibrations of the percussed object, but it needs a very discriminating ear to isolate it from the other by-sounds. As to the sensation of resistance to which the author particularly directs attention as being "transmitted to the hand," I had none sufficiently perceptible to direct my judgment. With some dexterity and after frequent application I was able to outline, though only very coarsely the organs of the chest. An exact direction of the stroke with a tube vibrating so easily in one's hand is an impossibility and this becomes painfully evident

when one tries to percuss with it the dependent parts of the thorax in a patient lying in bed, or the axilla, or the apices. Over the latter, the determination of their height, the outlining of the acoustic fields of Kronig, all important in the examination of tuberculous subjects, and the discovery of smaller foci of infiltration, easily determined by the common method, could in no way be facilitated by the use of the tube. These negative results were corroborated by several able clinicians.

It does not seem to me, therefore, that this *inventum novum* is destined to supplant the old methods which in the proper hands reach a high degree of perfection and are based on scientific facts. Percussion is and will remain an art. An instrument, as such, I believe does not hinder perfection in it, though I do not make use of any, but a percussion tube that emits a sound of its own seems *a priori* unprofitable, to say the least.

PROBABLE PLACENTAL TRANSMISSION OF TUBERCULOSIS

JOHN R. WILLIAMS, M.D.
ROCHESTER, N. Y.

Because of the scarcity of data on the subject of placental transmission of tuberculosis, the following is deemed worthy of report.

Patient—Mrs. K., aged 30, American housewife, eight months pregnant.

History—Patient complained of cough, night sweats, failing appetite and loss of weight, she gave a family history of tuberculosis, one sister who had lived and slept with her having died of the disease a short time previously.

Examination—The chest anteriorly and posteriorly revealed typical signs of tuberculosis in apices of both lungs. There was a loss of weight of 20 pounds in ten weeks in spite of pregnancy. The sputum contained both elastic tissue and tubercle bacilli.

Subsequent History—One month later, patient in normal labor, gave birth to a full term, apparently healthy, 7 pound boy. The placenta and cord were immediately placed in 4 per cent formalin solution and sent to Dr. A. S. Warthin, Ann Arbor, Mich., for examination. The child was taken at once to another house, and was never afterward handled, nursed or brought in contact with the mother. He was fed on modified milk, and for about six weeks made fair progress, gaining slightly in weight. Then, in spite of the most studious care in feedings, he began to decline. He was taken to the Infants Summer Hospital at Ontario Beach and kept there for some weeks, but to no avail. The child, like the mother, now presented the typical signs of general tubercular involvement, which need not be detailed. At this stage both mother and child were taken to the same house, although they were isolated from each other and had different nurses. The mother declined rapidly after the termination of pregnancy, dying six months later. The child outlived the mother by only one month. Both patients were seen by several other physicians, all of whom concurred in the diagnoses.

Dr. Warthin, after a number of careful examinations, was unable to find any evidence of tuberculosis in the placenta. The child died and was taken to a distant point for burial at a time when I was absent from the city, hence a postmortem study was not made, which is unfortunate, inasmuch as it robs the case of the confirmatory evidence necessary for a positive demonstration.

The School Girl—Dr. James Fraunfelder, Canton, Ohio, states (*Ohio State Jour. of Med.*) that the development of the mind is largely dependent on the efficiency of the body, and that the expansion of the moral element so well expressed by the word "character" is similarly intertwined in such close relationship that neglect of a part is derangement of the whole.

New and Non-Official Remedies

THE FOLLOWING ARTICLES HAVE BEEN TENTATIVELY ACCEPTED BY THE COUNCIL OF PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR INCLUSION IN THE PROPOSED ANNUAL, "NEW AND NON-OFFICIAL REMEDIES" THEIR ACCEPTANCE HAS BEEN BASED LARGELY ON EVIDENCE SUPPLIED BY THE MANUFACTURER OR HIS AGENT, BUT TO SOME EXTENT ON INVESTIGATION MADE BY OR UNDER THE DIRECTION OF THE COUNCIL. CRITICISMS AND CORRECTIONS ARE ASKED FOR TO AID IN THE REVISION OF THE MATTER BEFORE FINAL ACCEPTANCE AND PUBLICATION IN BOOK FORM.

THE COUNCIL DESIRES PHYSICIANS TO UNDERSTAND THAT THE ACCEPTANCE OF AN ARTICLE DOES NOT NECESSARILY MEAN A RECOMMENDATION, BUT THAT SO FAR AS KNOWN IT COMPLIES WITH THE RULES ADOPTED BY THE COUNCIL.

W A PUCKNER, SECRETARY

(A list of all accepted articles is published on one of the advertising pages of *The Journal* in the first issue of each month.)

(Continued from page 1109)

DIACETYL-MORPHINE HYDROCHLORIDE

Diacetyl morphine hydrochloride $C_{17}H_{17}(C_2H_3O) NO HCl$ is prepared by dissolving diacetyl morphine in dilute hydrochloric acid concentrating the neutral solution by evaporation and crystallizing.

It is a white crystalline, odorless powder having a bitter taste showing a neutral reaction with congo and melting at 230 to $231^\circ C$. (446 to $447.8^\circ F$)

It is soluble in 2 parts of water and soluble also in alcohol but insoluble in ether.

Its aqueous solutions are precipitated by alkaline hydroxides the precipitate being soluble in excess of the reagent, and by alkaline carbonates. In other respects the reactions are the same as those given under diacetyl morphine (which see).

It is incompatible with alkalies and their carbonates, tannic acid and other precipitants of alkaloids. It is decomposed by mineral acids particularly when heated.

Actions and Uses—When given in small doses Diacetyl-morphine Hydrochloride has apparently no effect on any of the vital functions except respiration, which it renders slower, the volume of the individual respirations being increased, but usually not sufficient to compensate the slowing, the result being a diminution in the total amount of air respired. In large doses it may produce dizziness, nausea and occasionally constipation, and, in poisonous amounts, twitching of the extremities, great exhaustion, and dimness of vision may be added. The temperature becomes subnormal and the pulse rapid and thready. The habit is readily formed and leads to the most deplorable results. It is said not to produce costiveness. (This is not true, according to some observers.) It is readily absorbed from mucous membranes. It lessens irritability of the respiratory center, thus allaying cough, but does not depress the respiration as much as morphine.

On withdrawing the drug from habitués there is said to be a tendency to respiratory failure which may be dangerous.

Diacetyl-morphine and its hydrochloride are recommended chiefly for the treatment of diseases of the air passages attended with cough, difficult breathing and spasm, such as the different forms of bronchitis, pneumonia, consumption, asthma, whooping cough, laryngitis, and certain forms of hay fever. It has also been recommended as an analgesic, in the place of morphine in various painful affections.

Toxic symptoms should be treated by the administration of caffeine hypodermically and of hot coffee by the stomach. To avoid respiratory failure in the treatment of diacetyl-morphine addiction, it has been suggested to substitute morphine for the diacetyl-morphine and then treat the patient for morphine addiction.

Dosage— 0.0025 to 0.005 Gm ($1/24$ to $1/12$ grain) to adults 3 to 4 times a day, the maximum dose being 0.01 Gm $1/6$ grain. To children it may be given in doses varying from 0.0002 to 0.001 Gm ($1/300$ to $1/60$ grain), according to the age. Hypodermically it may be administered in the form of a 2 per cent solution in the same doses. It has been applied locally to the throat, to the uterus on tampons and by suppository for painful pelvic affections generally, but there is no evidence that it produces any local anesthetic action.

HEROIN

A name applied to Diacetyl-morphine, which see.

Manufactured by Farbenfabriken vorm. Friedr. Bayer & Co., Elberfeld Germany (Continental Color & Chemical Co. New York) U S trademark.

HEROIN HYDROCHLORIDE

A name applied to Diacetyl-morphine Hydrochloride, which see.

Manufactured by Farbenfabriken vorm. Friedr. Bayer & Co. Elberfeld Germany (Continental Color & Chemical Co. New York) U S trademark.

LECITHIN

The esters of oleic, stearic, palmitic or other fatty acid with glycerophosphoric acid combined with cholin, occurring in combination with proteids in many animal and vegetable tissues, especially in nervous matter and egg-yolk.

Lecithin is best prepared from egg yolk (in which it exists as vitellin) by dissolving out the lecithin by strong alcohol.

It is a yellowish brown waxy solid of peculiar odor, soluble in an equal volume of cold absolute alcohol, readily soluble in chloroform, petroleum benzine and fats, less readily in ether. It is insoluble in water but swells, giving the peculiar myeline forms and decomposes on prolonged contact. It is hygroscopic on exposure to air.

The alcoholic solution is precipitated by platinum or cadmium chloride. It is decomposed by alkalies with the formation of choline and trimethylamine. The ash contains phosphoric acid. The different lecithins contain from 3.84 to 4.12 per cent. of phosphorus and 1.73 to 1.86 per cent. of nitrogen. The ratio of nitrogen to phosphorus should be as 1 to 2.21.

Lecithin is incompatible with alkalies. It should be kept in well stoppered bottles and should be protected from the light.

Actions and Uses—Lecithin acts as a stimulant to nutrition and not as a direct nutrient. The number of the red blood corpuscles and the amount of hemoglobin are increased. There is also a slight increase in the proportion of large mononuclear leucocytes. The appetite is improved and there is a retention of nitrogen and a diminution in the excretion of phosphoric and sulphuric acids, indicating a storage of proteids. The uric acid is perhaps slightly diminished. Lecithin, even in large doses, is not toxic.

The ordinary diet contains from 5 to 15 Gm (75 to 225 grains), and some observers claim that the benefits of the administration of lecithin can be obtained by an increased use of lecithin-containing food (eggs, etc.) but others claim that the raw or combined lecithin is ineffective.

Lecithin is held to be useful wherever there is faulty nutrition or growth, and is especially recommended as an addition to cow's milk for artificially fed infants. If no improvement results after ten days' treatment it is stated that it is useless to continue the drug.

Dosage—It may be given by mouth in dose of 0.1 to 0.5 Gm (15 to 8 grains) per day in pill form before meals or, hypodermically 1 Cc (15 minims) of a 5 per cent solution in oil, daily. Infants one third of the doses.

SATURDAY, APRIL 6, 1907

EXPERIMENTAL GASTRIC ULCER.

The importance of discovering a definite method by which can be produced experimentally ulcers in the stomach that in every way are analogous to genuine human gastric ulcer needs no emphasis. The prevention and the healing of human ulcers would thereby unquestionably be promoted in various ways. Recently reports have been made of results in this field of experimentation which indicate that noteworthy progress is being achieved. Thus Turck¹ has shown that by feeding dogs for variable periods with large quantities of cultures of colon bacilli ulcers not unlike round or peptic ulcer in man may be produced in the stomach and duodenum. The exact mechanism whereby ulcers are produced under these conditions has not been worked out, but the indications point to a combination of local and general disturbances. It would seem that the method, if found by other investigators to give reliable and constant results, will prove of considerable value for the study of experimental gastric pathology.

By careful study of guinea-pigs used in testing diphtheria antitoxin, Rosenau and Anderson of the Hygienic Laboratory found that in more than one-half of these animals dying before the tenth day after injection of diphtheria toxin there is present a sharply defined area of congestion, hemorrhage, or ulceration near or at the pyloric extremity of the stomach. In no case was perforation observed. Animals that recover from sub-lethal doses of toxin may show evidences of having had this lesion and it would seem as if we have in diphtheria toxin a definite means for the experimental production of gastric ulcers, at least in the guinea-pig, and it is to be hoped that the possibilities of this method will be thoroughly investigated.

Probably the results obtained by Futterer² in rabbits have the greatest immediate bearing on the clinical and therapeutic phases of human gastric ulcer. So far as can be made out, Futterer's present method of procedure is to excise a small piece of the mucous membrane of the stomach and then to maintain the animals in a state of chronic anemia by administration of blood-destroying chemical substances. Macroscopically and microscopically the ulcers so obtained resemble the human ulcer markedly, like the human ulcer they appear to prefer,

so to speak, the pyloric region in the vicinity of the smaller curvature, and their chronic course is held by Futterer to be in large measure if not wholly dependent on continuation of general anemia. From the fact that anemia is so essential for the initiation and the continuance of experimental gastric ulcer, Futterer draws the conclusion that much may be accomplished by way of therapy, both preventive and curative, if the physician pay due regard to the condition of the blood. The apparent ease with which ulcers may be produced by Futterer's method indicates that it too may prove of service in the further experimental study of gastric ulcer, which naturally will concern itself with the finer mechanisms of causation, and with the effect of various means and conditions on established ulcers.

An interesting question arises in connection with these various methods and that is whether or not the ulcers produced by their means are alike in their essential features. In order to determine this point careful comparative morphologic studies must be made of the ulcers at the various stages of their development. In his ulcers Turck describes a remarkable hyperplasia of acid cells, the analogue of which does not seem to have been observed so far in the case of human ulcers. Now it would be interesting to learn if ulcers produced by other and different means are associated with this hyperplasia. Human material, especially such as would illustrate the earlier stages of the formation of ulcer, should be collected for careful study and comparison with experimental ulcers.

THE RELATION OF THE STREPTOCOCCUS TO SCARLET FEVER.

Notwithstanding the immense amount of investigation devoted to it, the etiology of the acute exanthemata still remains more or less of a mystery. It is true that in certain diseases, variola and scarlet fever for example, supposed protozoan parasites have been described which are thought to bear an etiologic relationship to these diseases. It can not be said, however, that these parasites have been generally accepted as the true causes of the diseases in question, for they have not yet been shown to be constantly associated with the lesions, and some observers even question their parasitic nature and regard them, like the so-called cancer parasites, as peculiar cell inclusions. In the case of scarlet fever the *Cyclaster scarlatinalis* of Mallory has not been generally accepted, for while some have conceded its parasitic nature others have denied this. The question of the etiology of this disease is still under discussion, and Dr Hektoen's paper in this issue of THE JOURNAL¹ gives in a terse and critical manner the views of those who are opposed to the view that scarlet fever is caused by a protozoon and believe that it is a form of streptococcus infection, and at the same time the objections to the streptococcus theory are impartially set forth.

1 THE JOURNAL A. M. A. 1906 xlv, 1753
2 Festschrift für Rindfleisch 1907, p. 81

As Hektoen's paper shows, there is much evidence which suggests a possible relationship between scarlet fever and some variety of the streptococcus. On the one hand we have proof that in the vast majority of fatal cases of scarlet fever the streptococcus is present, on the other hand we have the knowledge that streptococcus infections apart from scarlet fever may be associated with throat and skin symptoms almost indistinguishable from true scarlatinal infection. Not only are so-called surgical and puerperal scarlet fever of streptococcal origin, though not true scarlet fever, but in certain streptococcal throat infections skin lesions almost impossible to differentiate from the true disease may occur.

All this, however, is not evidence that the streptococcus is the actual cause of scarlet fever. It does show that this organism is very frequently associated with the disease and is probably responsible for the great mass of fatalities, but there is evidence that fatal cases of scarlet fever can occur, especially the fulminating ones, in which streptococci are not present. The lack of streptococci in the infectious skin scales, their relatively poor resistance as compared with the known resistance of scarlet fever virus, and their occasional complete absence in some fatal cases, make it seem likely that the streptococcus is not the cause of scarlet fever, but merely a secondary invader. It is well known that this micro-organism plays a similar rôle in smallpox, a type of disease analogous to scarlet fever. Even if we assume that the rôle played by the streptococcus is a secondary one, we must not forget that it causes most of the fatalities, and one of our constant cares in the disease should be to protect the patient from the first against possible infection from other patients who harbor streptococci.

GOVERNMENT SUPERVISION OF VACCINE VIRUS

The efforts recently made in Pennsylvania and Connecticut to secure the repeal of statutes making the vaccination of children a condition of their right to attend public schools recalls the unreasonable prejudice that still exists against this beneficent prophylactic.

The opposition to vaccination appears to rest on the fundamental declarations that it is useless and dangerous, and that its compulsory enforcement is an invasion of individual rights. With the evidence now available it would seem that its utility must be conceded, for if there is one measure in preventive medicine that has been demonstrated beyond question it is that vaccination, properly performed, affords protection against smallpox. Individual license to do as one pleases is not an inalienable right, and community life denies the individual that privilege, especially if in so doing he becomes a menace to the public health. By a uniform course of decisions the courts have upheld the legality of laws requiring vaccination as a condition precedent to the right to attend school.¹ The right of

the community for the public welfare to enforce vaccination has also been affirmed. The dangers of vaccination, greatly exaggerated at all times, have now been reduced to a minimum. Practically the only danger remaining is accidental infection such as may occur in any open wound. This, in vaccination wounds, may be eliminated in a great measure by observing careful technic in performing the operation.

Reference has previously been made² to the beneficial results following the government control of vaccine virus, and it is now understood that, in accordance with an additional regulation issued March 13, 1906 by the Secretary of the Treasury, at the instance of the Public Health and Marine-Hospital Service, each lot of vaccine virus must be examined bacteriologically by the manufacturer to determine its freedom from pathogenic micro-organisms, and a special examination is required of every lot to determine the absence of tetanus. This supervision is no doubt largely responsible for the improved character of the vaccine virus now offered on the market in this country.

The Annual Report of the Public Health and Marine-Hospital Service, just issued, contains a list of establishments manufacturing this product under government license. Samples of the products of these firms are purchased from time to time on the open market and examined in the Hygienic Laboratory for purity and potency. These laboratory examinations indicated great improvement in the quality of vaccine virus following the administration of the law approved July 1, 1902 regulating the manufacture, barter and sale of viruses, serums, toxins and analogous products. With the view of obtaining information as to whether or not the practical results coincided with the laboratory data, the Surgeon-General addressed a circular letter to local health officers throughout the country for facts concerning the relative incidence of sore arms accompanying vaccinations during the winter 1904-1905 as compared with previous seasons. Nine hundred and fifty-one replies were received to this inquiry, of which 237 gave no data. 8 of the replies stated that there were more sore arms reported, one of these however attributing the complication to other causes than the character of the virus, 52 stated that they had not observed any difference in the number of sore arms during the year while 551 reported that there had been fewer sore arms.³ It is known that the operation of this law has prevented the sale in interstate traffic of "green" virus and from this report it is evident that marked improvement in the character of vaccine virus has taken place.

Evidence of this character should be carefully considered by legislative bodies before action is taken looking to the repeal of vaccination laws now on the statute as such a step can but be regarded as a retrograde step in preventive medicine.

THE HOUSING PROBLEM

The relation of the dwelling to health constitutes a problem, the seriousness of which the medical profession in this country has not yet fully appreciated. To the physician in Europe it appeals with force, since the defects of housing, especially of the lower classes, are much more apparent there than here. In Berlin, according to E. Roth,¹ 43 per cent of all householders live in apartments of one room, and that often unheated, and more than 70 per cent must be content with one or two rooms as the most comfortable dwelling which they can afford. These miserable conditions are made worse by the fact that the rent of such rooms is so high that it must be reduced by taking lodgers or roomers. The number of people to a house tends to increase as time goes on, having risen in Berlin from 71 to 77 in the decade from 1890 to 1900. In addition to the danger to health from overcrowding, problems are presented in consequence of dampness, insufficient light and poor ventilation, which are of vital interest to the physician. Roth attributes rheumatism, catarrh, colds and an increased susceptibility to infection to the dampness of the apartments, especially of those used for sleeping. This defect may be due to the improper use of the house especially for washing, drying clothes, etc., but much of the dampness is due to faults in the location or construction of the building. Another important matter in relation to health resulting from the location of the dwelling is the noise occasioned by factories, railroads, and street traffic. Some of this noise is unavoidable in a large city, while part of it may be lessened by judicious police regulations, but the power of the police is limited to suppressing such noises as can be shown to be detrimental to the health of the citizens. The exact effect of such noise is undetermined, but it is probable that it is a factor in the causation of that product of modern civilization, neurasthenia.

In this country the increasing popularity of flat life is creating a problem that sooner or later must be met and solved. Such a life is essentially an unnatural one. A majority of flats, although provided with modern conveniences in the way of heat, water supply and artificial light, are so constructed that one or more of the rooms can never be exposed, either directly or indirectly, to the sun's rays, in many cases requiring artificial light for their illumination. That such rooms furnish ideal conditions for the development of germ life is evident. Too often it is the case that bedrooms or water closets are ventilated and lighted only by an air shaft—and thus, too, in the apartment buildings of the better grade. Such conditions are inimical to the health of those living in such a building. To the health of the housewife in particular is flat life prejudicial. Add to the unnatural excitement of city life the lack of facilities, in the way of gardening, etc., for her to get near to Nature and the psychical effect of being more or less

closely confined within the narrow limits of her apartment, and we have conditions that predispose to the development of any latent neurotic tendencies which may exist.

The regulation of building and the provision of sanitary dwellings is emphatically a medico-social function, in the performance of which the physician must take a leading part by virtue of his special knowledge. He can be of assistance in framing suitable laws and in advising proper police regulations. The German physician comes in touch with this problem also through his services to the societies for industrial insurance against illness. The American physician, although less likely to find such a sphere of influence, will have abundant opportunity to advise his private patients regarding their choice of a residence. While the housing problem is not as acute in America as in Europe, we should not allow the opportunity to pass for the establishment of laws and regulations which will prevent the development of a situation so favorable to disease and immorality. By acting with a wise foresight, we shall be fulfilling our highest duty as guardians of the public health.

THE NUMERICAL RELATION OF THE SEXES

Statistics of births are now complete enough to afford a fairly reliable basis for some interesting conclusions. These are made the subject of an elaborate study by J. B. Nichols,¹ who has obtained data aggregating 693,785,722 living births and 13,635,986 stillbirths, or 707,421,708 births in all. These data are chiefly supplied by the exhaustive compilation of birth statistics published in *Statistique générale de la France*² supplemented by some data from original and other sources. The statistics regarding illegitimate births are of questionable value in consequence of the incomplete report and registration of these births, and, therefore, the estimate of total births is subject to some doubt. Some problems relating to the proportion of sexes have either received insufficient investigation or the data are imperfect so that a definite conclusion can not be given. This is true of the relations to war, climate, race, country and city, age, vigor, and social and financial condition of the parents, etc. Leaving these out of consideration, the principal conclusions established by this study are: The proportion of males to females at the age of differentiation of the sexes is higher than at any subsequent period and closely approaches the ratio of 1,063 sons to 1,000 daughters, more male fetuses die during pregnancy than female, and more males are still-born than females, so that the proportion of males to females among children born living averages, among peoples of the white race, 1,057 to 1,000. Among illegitimate children the proportion of males to females is lower, both of those born living and of those who perish during pregnancy, than in the case of legitimate births. The greater relative mortality of the male sex extends

¹ Mem. American Anthropological Assn. February 1907. I part 4.

² Statistique annuelle du mouvement de la population 1903 xxxiii

in a marked degree through the first year of life and in a diminishing ratio thereafter. These statistics seem to indicate a slight relative weakness of the male sex which, after all allowances have been made for accidents at birth in consequence of larger size, seems to exhibit less power of resistance to the causes of disease than the female. The proportion of sons is greater in large families than in small ones, Nichols asserts, but progressively decreases as the number at a birth increases. After all, however, while these studies and deductions are interesting and suggestive, they can not be regarded as safe bases for forming conclusions that may be accepted as satisfactory.

THE AGE LIMIT

Railroad managers, who are generally understood to know their own interests and those of the corporations under their charge, are undergoing apparently a change of views, at least in some cases, as to the expediency of excluding men of full majority or middle age from employment. If this is as we must suppose the result of experience, it means that the man of over 35 has been found to have still a reasonably long period of usefulness before him, even in the trying duties of a railroad employé. Heretofore it has been the theory that it is not profitable for roads to employ men over this age, and this, it seems, has been found too narrow a limit. While there is no doubt that many men are at their best efficiency before the fourth decade has passed, it does not necessarily follow that this is always the case or that there are not frequently greater possibilities for usefulness after that period than before. General rules are not capable of too universal application, and there are many occupations in which a rigid rule regarding age limit would be unprofitable. The fact that the railroad companies are apparently beginning to recognize this truth is significant. Young men will always be to the fore in many lines, but much of the best work will always be done by men somewhat more advanced in years. It is probable that of late years we have placed the age limit unreasonably low.

SANITATION AND ETHICS

In a recent issue of *THE JOURNAL*¹ editorial notice was given to the statements of Dr. Solis-Cohen regarding the sanitary effects of some of the Jewish ritual observances. The Jewish religion is not altogether peculiar in this respect and Christianity has inherited from the Jews some valuable sanitary practices, one of the most important of which, the seventh day rest, was not specially emphasized by Dr. Solis-Cohen. That it is not universally observed in Christian populations is admitted, but that it would be better if it were probably no physician would deny. The institution of Lent was undoubtedly a saving ordinance from a sanitary point of view during a considerable period of the world's history, and in many countries it probably still has a beneficial effect on the public health. The change from

a salt meat diet, which was for many centuries largely the rule during the winter months in Europe, to a more or less exclusively vegetable one was a salutary measure that would hardly have been thought of, much less adopted, save for the injunctions of religion. In some respects, however, religious practices have been directly insanitary, and this was particularly the case during the Middle Ages under the influence of the asceticism of that time. Taking into account other religions than Christianity one would not have to look far for plenty of evidence of the conflict between religious observances and enlightened sanitation. Christianity and Judaism stand almost alone among religions in that regard for human life and welfare which is the basis of all sanitary regulations. Even in the most enlightened of heathen nations sanitary science is practically non-existent save where it has been introduced through the influence of Christian nations. Whatever is conducive to the moral well-being of a people also raises its physical standards and so far as religions conform to moral concepts so far are they favorable to physical as well as to moral welfare. The sanitarian in his practical teachings is not in his theories, is also a moralist. This is a truth that does not always appear as self-evident as it should.

THE MEDICAL INSTITUTE' S TRAUDS

Advertising quacks, having as a rule a certain definite line of treatment (?) for all patients have long been known to fabricate the diagnoses of their victims ailments to suit such treatment. The knocking down of these men of straw, in fact, constitutes the theatrical side of their business. Most of these concerns at least have been consistent enough to have some slight degree of relationship between their diagnoses and their treatments. In the suit instituted against the "Wisconsin Medical Institute" recently mentioned in these columns it appears that even the element of consistency is sometimes lacking. According to the testimony of the "doctor" employed by the institute not only were false diagnoses given, but the treatment (?) instituted would not have helped the patients even had the diagnosis been correct. The testimony was fortified by the fact that the physician in question was an unwilling witness and that his statements had to be drawn out by sharp questioning on the part of the state's attorney. Medical and surgical institutes of the advertising type have been profitable concerns in the past and such testimony indicates the reason. A few more prosecutions actively carried out and the details thoroughly ventilated in the public press, ought not only to put some of these concerns out of commission but give the business generally a sort of advertisement that would make it less profitable in the future. Unfortunately the worst of the establishments are the most invulnerable on account of the difficulty of obtaining the testimony of those who have put their reputations in their power.

Farming for the Insane—I am fully convinced that a thoroughly equipped farm properly conducted is the best method to the cure of the insane than any other resort to.—W. L. Taylor, M.D.
Commons

¹ *Ritualistic Sanitation of the Jews*. *THE JOURNAL*, March 2, 1907, 801.

Medical News

ALABAMA

Sputum Cups—Dr Gaston J Greil, health officer of Montgomery, will distribute gratis 500 sputum cups to consumptives who apply.

Hospital Notes—Dr J C Moore, Anniston, has converted his residence into a private sanitarium, with accommodation for eight patients. The hospital will be open for the use of the practitioners of the city.

Personal—Dr Richard F Michels, Montgomery, celebrated on March 9 the sixtieth anniversary of his entering the practice of medicine—Dr Shirley Bragg, Montgomery, was recently appointed state inspector of jails, almshouses and cotton factories—Dr John W Watts, Birmingham, has been selected as physician for the Birmingham convict camp, and Dr John C McLeod, Bay Minette, for the Dohle camp.

Society Meeting—The De Kalb County Medical Society, at its annual election, held at Fort Payne, elected Dr Sidney J Vann, Collinsville, president. Dr William S Duff, Fort Payne, vice president, and Dr William E Quinn, Fort Payne, secretary treasurer—At a meeting of the Medical Society of Colbert County, held in Tusculum, March 21, the following officers were elected. President, Dr Taylor H. Henry, vice president, Dr Julius T Haney, and Drs H W Blair and Morris Henry, censors.

Government Takes Over Quarantine—On April 1 the United States Public Health and Marine Hospital Service has directed Dr Edward Francis, in charge of the Mobile Marine Hospital, to assume control of quarantine at Mobile and to begin the inspection at Fort Morgan of all tropical vessels. Dr Rhett Goode, president of the quarantine board of Mobile Bay, has been advised that the government has approved the sale of the local quarantine station and has received a check for \$18,000, covering the purchase.

Medical College Transfer—At a meeting of the faculty of the Medical Department of the University of Alabama the building and contents formerly known as the Mobile Medical College was turned over to the medical department of the university. The present members of the faculty were reappointed. The first payment on the appropriation made by the state for the improvement of the institution will, it is understood be made April 1. Commencement exercises of the Medical Department of the University of Alabama will be held April 15.

ARKANSAS

Physician in Trouble—Dr Oscar S Burrow, Hot Springs, charged with violating the drumming ordinance, was found guilty and his license to practice was revoked and a fine of \$100 assessed.

Personal—Dr W B Welch Fayetteville, was seriously hurt by a fall at Fort Smith March 20—Dr A L Carmichael, Little Rock, has been elected by the State Board of Charities to fill the unexpired term of Dr A J Harrison as physician for the charitable institutions.

Society Meetings—The Saline County Medical Society, at its recent meeting held at Benton elected Dr John W Melton, Alum, president. Dr Charles Prickett, Traskwood, vice president and Dr Charles J Steed Hurricane secretary treasurer—At the annual meeting of the Lincoln County Medical Association, held at Star City the following officers were elected. President Dr J K McClain Star City, vice-president, Dr John T Palmer Varner secretary treasurer Dr Benjamin F Turner Star City, censors, Drs W C Kimbro, Tyro, and Charles W Dixon, delegate to the state medical association, Dr John T Palmer Varner and alternate, Dr J F Johns—At the annual meeting of the Tenth Councilor District, or Northwest Arkansas Medical Association, held at Fort Smith, March 20 about fifty members were present. Dr J N McCormack delivered an address to the public at the high school auditorium and the following officers were elected. President, Dr W N Yates Fayetteville, vice-president Dr James J Smith Paris secretary Dr James A Foltz Fort Smith, treasurer Dr O M Bourland Van Buren Fayetteville was selected as the place for the next meeting.

CALIFORNIA

Building for Physicians—The Sawyer building, eight stories high of steel construction at present being erected at Sutter and Jones streets San Francisco, is built to meet the special requirements of physicians and dentists. The building will cost \$300,000 and is expected to be ready for occupancy April 1, 1908.

Personal—Dr Percy Sumner has resigned as medical physician of the California State Prison and Dr W M Thorne has been appointed to fill the vacancy. Dr Sumner is going to take graduate work on the eye, ear, nose and throat in the East—Dr Charles B Pinkham has been appointed chief surgeon of the Western Pacific Railway, with headquarters at San Francisco—Dr Charles Freedman, Los Angeles, chief police surgeon at the Receiving Hospital, has resigned—Dr Chauncey Wilder, Oakland, formerly of Elgin, Ill., shot and killed a burglar who was trying to enter his house March 15—Dr A A Stafford, San Francisco, is expected to return from New York early next month—Dr F M Pottenger, Monrovia, will leave for a four months' trip to Europe about April 1.

Society Elections—At the annual meeting of the Solano Medical Society, held at Vallejo, March 14, the following officers were elected. President, Dr C E Turner, vice president, Dr J W Huckins, secretary, Dr J J Hogan, and treasurer, Dr Fred T Bond—The twenty third semi annual meeting and banquet of the San Joaquin Valley Medical Society was held at Hanford, March 12. Dr W T Barr was elected president, Dr Fowler, vice president, Dr D H Trowbridge, secretary, and Dr T M Hayden, treasurer—The Central California Health Officers' Association, at its meeting in Hanford, March 11, elected Dr R W Musgrave, Hanford, president, Dr S W R Langdon, Stockton, vice president, Dr John R Butin, Madera, secretary, and Dr G L Long, Fresno, treasurer.

COLORADO

Personal—Dr Francis B Rothrock, Colorado Springs, was run over after a breakdown of his buggy and was painfully injured—Dr and Mrs Horace G Wetherill, Denver, are taking a tour in Europe—Dr Michael Bashoar, Trinidad, has been elected vice president of the American Tuberculosis League.

Society Meetings—At the annual meeting of the Fremont County Medical Society, held in Florence, Dr Royal C Adkinson, Florence, was elected president, Dr Pitt A Wade, Canon City, vice president, Dr Raynor E Holmes, Canon City, secretary treasurer, and Dr Wilbur T Little, Canon City, delegate to the state association—The Teller County Medical Society, at its annual meeting held in Cripple Creek, elected the following officers. President, Dr Will F Hassenplug, Cripple Creek, vice-presidents, Drs Benjamin F Jones, Goldfield, Walter W King, Cripple Creek, and Albert C McClanahan, Victor, secretary, Dr Thomas A McIntyre, Cripple Creek, treasurer, Dr Alfred J Campbell, Victor, and delegate to the state association, Dr Albert C McClanahan, Victor.

ILLINOIS

Health Bill Progresses—House bill No 408, amending the State Board of Health Act of 1877, passed the House of Representatives March 28 by a vote of 89 to 1. There has been no further change in the status of the other bills previously noted in THE JOURNAL.

State Board Orders Prosecution—Acting under directions from the secretary of the State Board of Health, the state's attorney at Peoria is reported to have instituted proceedings against C M Tharp, Kingston Mines, for practicing medicine without a license. A judgment was, it is reported, found against Dr Tharp in 1902 for the same offense, and Dr Egan has instructed the state's attorney immediately to collect the penalty of \$200 prescribed in this case.

Chicago

In Aid of Hospitals—The concert at Orchestra Hall, April 1, netted \$3,000 for St Mary of Nazareth Hospital—The Fresh Air Fund for the Jackson Park Sanitarium for Babies was increased by \$2,000 as the result of a benefit performance, March 28, at the Garrick Theater.

Cocain Seller Fined—Albert Dahlberg, against whom the police have been waging a crusade for selling cocaine, pleaded guilty March 28, and was fined \$150 and costs by Municipal Judge Newcomer. He was also put on probation and ordered to report to the court every two weeks.

A High Death Rate—The death rate in Chicago is unprecedented in the history of the health department. During the week ended March 30, 744 deaths were reported equivalent to an annual death rate per 1,000 of 18.40. The death rate for the corresponding week of 1906 was 14.80 per 1,000. Pneumonia caused 172 deaths, consumption, 85, heart disease, 55, nephritis, 45, violence, including suicide, 40, cancer, 34 and acute intestinal diseases, 30.

Communicable Diseases—During the week ended March 30, 169 new cases of scarlet fever were reported, with 16 deaths, 88 cases of diphtheria, with 8 deaths, a decrease in new cases of 33 in the case of scarlet fever and 35 of diphtheria, as com-

pared with the preceding week. An increase of 18 cases of measles was noted, 126 cases being reported for the week. No cases of smallpox have been found during the week, and the Isolation Hospital still contains 17 patients.

IOWA

Tuberculosis Hospital Site—Two pieces of property west of the Iowa River, near Iowa City, have been deeded to the state as a site for the new tuberculosis hospital, to be built at a cost of \$70,000. The actual building of the hospital is expected to begin during the summer.

Smallpox—The prevalence of smallpox at State Center has necessitated the closing of churches and schools and the interdicting of public gatherings. Four cases of smallpox are reported from Davenport. The public schools of Anita have been closed on account of smallpox, three cases of the disease having been reported. Clemons is reported to have two cases of smallpox.

College Officers and Faculty Elected—Dr. Frederick E. Franchère was elected president of the board of trustees of the Sioux City College of Medicine at its annual meeting. Dr. R. H. Munger was elected vice president, Dr. Edwin D. Frear, secretary, Dr. Robert M. Gallen, professor of materia medica, Dr. Howard N. Brothers, professor of therapeutics, Dr. William Gillaume, professor of diseases of children, Dr. Frank S. Johnson, professor of diseases of the nervous system, and Dr. Frederick A. Franchère, professor of diseases of the eye, ear, nose and throat. Drs. William S. Tharp and Edwin D. Frear were elected members of the board of trustees, and Dr. John A. Dales was re-elected a member of the board.

Personal—Dr. Charles E. Ruth, Keokuk, on the eve of his leaving for his new home in Colorado, was the guest of honor at a banquet March 16, given by his professional brethren of Burlington. Dr. Ira D. Kauffman has been appointed health officer of State Center, vice Dr. Elmer W. Coe, resigned. Dr. William O. Parish, Osceola, on the occasion of his sixty-eighth birthday was presented with a Morris chair by the Clark County Medical Society, of which he is president. Dr. Alden H. Wight, New Hampton, was stricken with cerebral hemorrhage, March 16. Dr. Schroeder, Traer, has returned from Germany. Dr. and Mrs. Isaac E. Nervig, Sioux City, were injured in an ice avalanche at Niagara Gorge, March 12. Dr. Russell I. Hemphill, Plymouth, was thrown from his carriage in a runaway accident recently, suffering severe cuts and bruises.

KANSAS

Epidemic Diseases—More than 60 cases of measles were reported in Fort Scott. Measles is reported to be epidemic in Leavenworth. More than 1,000 high school students of Topeka were recently exposed to smallpox and ordered vaccinated. Topeka has at present 9 smallpox patients in the Isolation Hospital. During the first 18 days of March more than 100 cases of contagious diseases were reported and placed under quarantine at Topeka. The health officer of Wichita reports 42 cases of smallpox in that city. It is reported that there are more than 40 cases of smallpox in Hutchinson.

Hospital Notes—Evergreen Hospital, a private sanitarium at Leavenworth, was destroyed by fire March 18, with a loss of \$60,000. The inmates escaped uninjured. The Planters' House, Leavenworth, is to be used as a sanitarium until the management of the hospital secures permanent quarters. The Commercial Club of Topeka has taken on itself the responsibility of securing a site for the proposed Sisters of Charity Hospital in that city. The sisters will build a hospital to cost between \$25,000 and \$50,000, on the condition that the city furnishes a site. The governor has authorized an addition to the Post Hospital, Fort Riley, to cost \$35,000. The hospital was built last year at a cost of \$40,000.

KENTUCKY

Epidemic Diseases—Sharpsburg and its vicinity are said to be suffering from an epidemic of influenza. Measles is reported to be epidemic at Paducah. On account of the prevalence of scarlet fever at Borden the public schools have been closed.

Academy Officers—At the annual meeting of the Louisville Academy of Medicine Dr. J. Rowan Morrison was elected president, Dr. Hugh R. C. Manning vice president, Dr. Oscar F. Bloch secretary and Dr. Cavin Fulton, treasurer. Dr. Daniel M. Griffith Owensboro president of the state medical society was the guest of honor.

Tuberculosis Clinic—The Kentucky Anti-Tuberculosis Association has deeded to purchase 53 acres between Taylor Boulevard and the Eighteenth Street road, Louisville, for \$13,300 on which a hospital will be erected. The association has ar-

ranged to hold two clinics a week at the City Hospital and to furnish a visiting nurse free to the poor, the city to provide quarters and medicine.

Incorporated Milk Commission Inadvisable—At the last meeting of the Jefferson County Medical Society the milk commission deemed it not advisable to incorporate the commission, as had been suggested at the last meeting as the state pure food authorities had in charge all legal matters which might arise. The commission reported that of three supplies of certified milk all had a bacterial count of less than 5,000 and one of these a count of only 1,000, the standard being 10,000 per c.c.

Personal—Dr. and Mrs. Joseph M. Mathews, Louisville, have returned after three months in Florida. Dr. William A. Keller, city physician for the west end, Louisville, is reported to be critically ill. Dr. William T. Willis, Mount Sterling, recently pushed his right arm through a glass window, cutting an artery and nearly bleeding to death. Dr. Joseph W. Hill, formerly of Bardstown and for the last four years superintendent of the Kentucky Institute for the Education and Training of the Feeble Minded Children, Frankfort, has resigned to enter private practice and will probably settle at Versailles.

Eradication of Bovine Tuberculosis—A special meeting of the Kentucky Veterinary Association was held at the Galt House, Louisville, March 28, in the interest of a measure to be introduced in the next legislature for the eradication of tuberculosis among dairy cattle. During the discussion two of the local veterinarians made the statement that the inspection of dairies as now practiced by them is a farce, that it is easy to make money by driving to a fence along side a dairy, asking the number of cows in the herd, writing a certificate that they are healthy and receiving 50 cents a head therefor. It was stated that 25 to 35 per cent of the cattle supplying milk to Louisville are tubercular, and a still larger percentage around Covington.

Faculty Officers of Merged Colleges Elected—At a meeting of the combined medical faculties of the University of Louisville and Kentucky University to be known in the future as the Faculty of the University of Louisville Medical Department, held March 27, in Louisville, the following officers were elected: President, Dr. James M. Bodine, dean, Dr. Thomas C. Evans and secretary, Dr. Richard B. Gilbert. Dr. Bodine, in accepting the office, stated that with the present session he was rounding out his fortieth year as dean of the university and that it was with regret he relinquished it for the more responsible position of president of the faculty. An advisory committee was appointed composed of the chancellor, Dr. John C. Willis, Joseph B. Marvin, Thomas L. Butler, Adolph O. Pfingst and John G. Cecil. This committee with the faculty, will have in charge the details of the college work.

MARYLAND

Fight Against Consumption—Nearly \$5,000 of the \$10,000 fund required for the work of the Maryland Association for the Prevention and Relief of Tuberculosis has been subscribed. A branch of the society has been organized at Hagerstown with Dr. James W. Hummelhouse as vice president and Dr. Christian R. Scheller as treasurer.

Personal—At a meeting of the Society of Colonial Wars held March 28, the anniversary of the settlement of Maryland, Dr. Bennett B. Browne was elected librarian and Dr. H. Barton Jacobs, surgeon. Dr. Brice W. Coldenborough, Cambridge, is ill at Johns Hopkins Hospital, Baltimore. Dr. Charles G. W. MacGill is ill at his home in Catonsville.

Bequests—By a decision of the Circuit Court, March 18, the Union Protestant Infirmary, Baltimore, received a legacy of \$1,000 devised to it in 1901 with interest from that date. The late Martin Kelly, Baltimore, after some small bequests, devised one half the residue of his estate to St. Agnes Sanitarium. Moses Pels, a wealthy shoe dealer of Baltimore, has empowered his executors to make certain charitable bequests, no stipulation as to the amount or the institution being made.

Insanity on the Increase—According to the twenty-first annual report of the lunacy commission prepared by the secretary, Dr. George J. Preston, Baltimore, in 1911, there is an increase in Maryland. Additional accommodation must be provided for the indigent in care and the coming year will be called on for an increased appropriation to this effect. Causes of insanity named in the report are: (1) coming next, (2) employment is carried on, (3) the chronic in care, when the cause is not permitted its use.

MASSACHUSETTS

Mueller in Boston—Dr Friedrich Mueller, Munich, spoke March 27 before the Boston Medical Society on "Social Legislation in Germany and Its Influence in the Care of the Sick."

Alumni Association Meets—The Western Massachusetts Alumni Association of the Medical Department of the University of Vermont, Burlington, held its third annual banquet at Springfield, March 21. The guest of honor was Dr Henry C Tinkham, Burlington, dean of the medical school, and Dr Charles J Downey, Springfield, officiated as toastmaster. The following officers were elected: President, Dr Charles J Downey, Springfield, vice president, Dr James M Fay, Northampton, and secretary treasurer, Dr Mortimer J Stoddard, Springfield.

Epidemic Diseases—The White Star Liner *Oymric* was held at quarantine, March 25, on account of a case of smallpox on board. The thousand steerage passengers were vaccinated before the steamer was released. Because of the number of cases of scarlet fever in Boston, the Board of Health has asked an increase in its appropriation from \$210,000 to \$240,000. At the annual town meeting of Brookline, \$238,178 was appropriated for the public safety and health account. A sophomore at Harvard is reported to have died at the college hospital, March 20, from spinal meningitis. Fourteen cases of variola were reported in Lawrence, March 24, and seven more developed during last week. The disease is in mild form, and the patients have all been removed to the Isolation Hospital.

NEW YORK.

More Typhoid at Katonah—Three new cases of typhoid fever have been reported at the village of Katonah. Dr Darlington has gone over the entire territory and found everything in a hygienic way apparently as it should be, and contamination of the city water supply seems impossible.

Sanitarium Gabriels—This institution, which is located in the Adirondacks and cares for those in the first stages of tuberculosis, is seriously handicapped by lack of funds and asks \$65,000, of which \$8,401 must be raised before May 24. About \$135,000 has already been spent on buildings and equipments.

New State Hospital—The State Lunacy Commission wants the state to buy a site for the building of a hospital on the cottage plan and has drafted a bill for passage by the legislature providing for this. The state's lease of Ward's Island expires in five years, therefore, future disposition of the many patients there now necessarily occupies the commission's attention.

New York City

Personal—Dr Mary Crawford has been appointed to the surgical staff of the Williamsburg Hospital. Dr and Mrs John J Nutt sailed on the *Pennsylvania* for Hamburg, March 30.

Tablet to Dr Fowler—The Society of Ex Internes of Seney Hospital Brooklyn will unveil a bronze tablet to the memory of Dr George Everson Fowler. The tablet will be placed in the main hall of the hospital.

Pneumonia on the Increase—According to the winter report of the Board of Health during the period from Dec 8, 1906 to March 9 the deaths from pneumonia in Greater New York were 4,105, while those from tuberculosis numbered only 2,496.

Talk on Charity—Attorney General Bonaparte delivered a lecture at Carnegie Hall from which the Society of St. Vincent de Paul realized \$2,000, which will be devoted to its charitable works in this city and its fresh air farm at Spring Valley.

Appeal for Samaritan Hospital—A movement is on foot to raise \$200,000 for the erection and equipment of Samaritan Hospital. This hospital is the outgrowth of a dispensary established six years ago because of the rapid growth of the section in which it is located. The hospital was incorporated in 1904.

Milk Hearing Ends—The last public hearing before the committee of aldermen, on the subject of pasteurization of the city milk supply, was held March 29. In view of the stand taken by the Board of Health and endorsed by the Academy of Medicine, the scheme for wholesale pasteurization was given up though the crusade for better conditions in the dairies will be prosecuted with diligence.

Glasses for School Children—At the last meeting of the Board of Education there was a spirited discussion over the question of furnishing glasses for school children with defective vision. It was stated that 36,000 children in the schools are suffering from defective vision, and that the ma-

jority of the parents of these children are unable to furnish them with glasses. A resolution was appended to this report asking for \$30,000 to fit up rooms for testing eyes and for the provision of glasses, etc. The resolution was laid over until the next meeting.

Better Hospital for Immigrants—The plans for the improvement of the immigrant station at Ellis Island and for the completion of the huge contagious diseases hospital which is being built on a small artificial island adjoining Ellis Island, will be completed by July 1, when the appropriation will be available, and the work will be rapidly pushed to completion. The recent Congress appropriated \$850,000 to be expended on these improvements. Of this sum \$400,000 is for remodeling the main building, and \$250,000 was added to a former appropriation for the hospital.

City Hospitals Full—The Commissioner of the Charities Department has presented a report to the State Board of Charities telling of the overcrowded condition of the various hospitals and institutions under his care. During the coming month he will act on bids for the construction of city buildings to cost \$2,000,000. The Sea View Hospital for tuberculosis patients on Staten Island had been halted by an injunction obtained by real estate dealers and owners who claim that the institution is for contagious disease and should be under the management of the Health Department. The city has over 10,000 helpless persons to care for and, owing to the growth of population and the influx of immigrants, is confronted with a difficult problem. Even at present all the institutions for the care of this class are overcrowded and the improvements now under way should have been completed years ago.

Contagious Diseases—There were reported to the sanitary bureau for the week ended March 16, 435 cases of tuberculosis, with 209 deaths, 429 cases of measles, with 13 deaths, 365 cases of scarlet fever, with 25 deaths, 256 cases of diphtheria, with 37 deaths, 55 cases of typhoid fever, with 4 deaths, 45 cases of whooping cough, with 9 deaths, 21 cases of cerebrospinal meningitis, with 16 deaths, and 106 cases of varicella, a total of 1,712 cases and 313 deaths. There were reported to the sanitary bureau for the week ended March 23, 410 cases of tuberculosis, with 109 deaths, 44 cases of measles, with 13 deaths, 375 cases of scarlet fever, with 19 deaths, 318 cases of diphtheria, with 34 deaths, 101 cases of typhoid fever, with 17 deaths, 61 cases of whooping cough, with 12 deaths, 21 cases of cerebrospinal meningitis with 18 deaths, 99 cases of varicella and 3 cases of smallpox, a total of 1,832 cases and 282 deaths.

PENNSYLVANIA.

Diphtheria Epidemic—Diphtheria has become so prevalent at Intercourse, near Lancaster, that the school board has closed the public schools and will not have them reopened this spring.

Must be State or Private Hospitals—Governor Stuart has vetoed a bill for mixing state and private management of hospitals, a practice well established in the state. There are hospitals that will not accept state aid, but there are others that accept it under the present system, but would refuse it rather than submit to partial state control. The bill directed the governor to appoint two directors or trustees of all institutions, hospitals, etc., which receive state aid for maintenance or other purposes. The state would not obtain control of the institutions, but only the means of interfering with private control.

Care of Insane Inadequate—The commission appointed by the last General Assembly to investigate the management of Pennsylvania institutions for the insane, submitted its report to the governor March 24. The commission finds that the housing or custodial care of the insane in the institutions supported by the state is totally inadequate and inefficient, because of the age and crowded condition of the buildings, that those responsible for the treatment and care of nearly 15,000 inmates of these institutions have not kept pace with the highest medical skill and science, that the laws and decisions fixing the responsibility of relatives and others for the support of the inmates have not been enforced, in consequence of which the counties have not been reimbursed in many thousands of cases and the state has not been reimbursed for money amounting to hundreds of thousands of dollars paid for the maintenance of such inmates, which should have been repaid by the estates of inmates or relatives responsible under the law.

Health Officers for Rural Districts Advocated—The cities and boroughs throughout the state are strongly advocating Health Commissioner Dixon's appointment of health officers

for the unprotected rural districts. There are about 2,500,000 people in the state who live in districts where there are no local boards of health. The 700 health officers appointed by Dr. Dixon for the rural districts will see that the regulations of the State Department of Health for the control of communicable disease are obeyed. The enforcement of such regulations in the case of scarlet fever and diphtheria, for instance, will be particularly beneficial. Not only will every case like this be placarded by the health officer, but on the termination of the case he will disinfect the premises properly. Following the placarding of such contagious diseases as require the exclusion from school of the children in the household, the township health officer will serve a written notice on the school in regard to such exclusion. He will also notify the libraries in the district, so that books may not be granted to those residing in infected houses.

Personal.—Dr. Herman A. Brav, Philadelphia, has been elected surgeon in charge of the department of rectal diseases in the American Hospital for Diseases of the Stomach.—Dr. B. Harry Warren, West Chester, has resigned as dairy and food commissioner of Pennsylvania. The salary of the office is \$2,500 a year.—Dr. Charles H. Saul, Steelton, who has been seriously ill for several weeks, is convalescent.—Dr. William E. Kunkle, Williamsport, is reported to be seriously ill at his home.—Dr. James S. Koontz, Johnstown, who has been ill for several weeks has recovered.—Dr. Alfred J. Yost and family, Allentown have returned from Denver.—Dr. Isaiah F. Everhart, Scranton, was recently stricken with cerebral hemorrhage, and is reported to be critically ill.—Dr. Austin M. Grove, York, has been appointed coroner of York County, to fill the unexpired term of Dr. Herbert F. Gross.—Dr. Sidney Davis, Milton, was thrown from his buggy in a runaway accident recently and severely cut and bruised.—Dr. Franklin F. Arndt, Scranton, has resigned as city bacteriologist, and Dr. Jonathan M. Wainwright has been appointed his successor.—Dr. Jesse G. Kistler, Germansville, who was recently injured about the head in a runaway accident, is reported to be critically ill with erysipelas.

Philadelphia

Protest Against Veterinary Hospital.—Dr. Henry W. Cattell writes that there was an error in an item in THE JOURNAL, March 30. He states that the act entitled "An act for the protection of the public health, prohibiting hereafter the establishment or maintenance of additional hospitals, pest houses and burial grounds in the built up portions of cities," and reading "that for the purpose of protecting the public health, it shall be unlawful hereafter to establish or maintain any additional hospital, pest house or burial ground in the built up portions, provided, however, that nothing herein contained shall be construed as to prevent the maintenance of any hospital, pest house or burial ground now lawfully established and maintained in such portions of the cities," which was approved by Governor Stone, April 20, 1899 was repealed four years ago, ostensibly for the purpose of permitting the Phipps Institute to establish its hospital for consumptives, but really with the object of allowing the University of Pennsylvania to erect its Veterinary Hospital at Thirty ninth and Woodland Avenue. Dr. Cattell condemns the health authorities of Philadelphia for the erection of the hospital, at which the most loathsome contagious diseases of the lower animals transmissible to man, are to be treated.

Hospital for Insane Open.—Improvements began under contract last November involving the expenditure of \$126,000 having been completed, the Philadelphia Hospital and addition for the insane was opened to the public March 27. As the male indigent were removed in September, 1900, to quarters in the Philadelphia Museums, the building formerly occupied by that class of inmates has been renovated and its new inmates were installed March 28. This renovation includes renewal of practically all floors, the cleaning and painting of walls, the displacement of all antiquated plumbing and the installation of the most modern appliances, the equipment of wards with new furniture, medicine closets, rolling chairs, stretchers and new linen. Other equally important improvements are the provision of new quarters in the old attic for 75 orderlies and attendants, new steam heating appliances with guards for protecting the sick and insane, metal screens for windows and doors, fire escapes with additional stairways all of which on the insane side, are properly enclosed and a new tunnel through which the insane may go to and from meals in inclement weather without exposure. It is hoped that the fresh air treatment for tuberculosis will soon be adopted on a large scale at the hospital. At present there are 286 tubercular patients, 223 males and 63 females.

TEXAS

Change in Hospital Plan.—The new hospital building to be erected at Temple for the use and benefit of the employees of the Santa Fe system at a cost of \$100,000, is to be made fireproof, at an additional outlay of \$20,000.

Epidemic Diseases.—Several well developed cases of small pox with one death are reported from Courtney.—Vaccination of all children in the public schools of Dallas was ordered March 8. Two physicians have been appointed for each ward school and the work is to be completed in one day.—The white and colored schools at Stafford and the colored school at Hockley have been closed on account of the prevalence of smallpox.

UTAH

Personal.—Dr. William R. Tyndale, Salt Lake City, has been appointed assistant surgeon in the National Guard of Utah, vice Dr. Hiram A. Anderson, Salt Lake City, resigned.—Dr. William R. Calderwood, Salt Lake City, has been appointed county physician.—Dr. Alfred J. Ridges, Salt Lake City, has been appointed assistant in anatomy at the Johns Hopkins Medical School, Baltimore.

Medical Board Named.—The governor has made the following nominations for members of the State Board of Medical Examiners: Drs. David C. Budge, Logan Cache County, Amasa S. Condon, Ogden, Weber County, Charles L. Olsen, Murray, Alexander C. Ewing, Salt Lake City, Elias S. Wright, Salt Lake City, Frederick E. Straup, Bingham Canyon, Robert W. Fisher, Salt Lake City, Ralph Richards, Salt Lake City, and A. P. Hibbs, Weber County.

Epidemic Diseases.—Several cases of diphtheria have recently developed in Ogden.—The county quarantine physician, Dr. Ferguson, Castledale states that the cases of small pox at Orangeville, Ferron and Clawson have recovered and the county is now free from the disease.—It is reported that there have been 24 deaths from cerebrospinal meningitis since January 1.—The inspector of the state board of health reports 14 cases of typhoid at Segirt, Sevier County.

Work of the Legislature.—The State Board of Health rejoices over the fact that its work in the legislature has been successful and that its attempts to raise the hygienic and sanitary standards of the state have been appreciated. The following bills have been passed. A bill compelling manufacturers of nostrums to show on a label whether alcohol or narcotics form a part of the formula, a bill providing for the instruction of children in public and normal schools in the prevention of disease and the causes of disease, a new pure food law, similar to the national pure food law, a bill to prevent expectoration in public places and street cars and requiring cuspidors to be placed in the day coaches on railroad trains, the marriage restriction bill was also passed.

VIRGINIA

Medicine Samples Barred.—Health Commissioner Henry R. Dupuy, Norfolk has refused to issue a permit for the distribution of samples of nostrums in the city.

Correction in List of Officers.—In the election of officers of the Richmond Academy of Medicine and Surgery published in THE JOURNAL, March 16, page 917 the name of the third vice president should have been Dr. Creer Baughman and that of the treasurer Dr. William A. Shepherd.

Dispensary Report.—During 1906 the dispensary of the Medical College of Virginia, Richmond treated 6,017 patients, 1,358 of whom were white and 4,659 colored. The surgical cases numbered 1,253, those of children's diseases 185, and 9,277 prescriptions were compounded at the dispensary.

Personal.—Dr. Oliver C. Brunk has assumed charge of the Eastern State Hospital for the Insane, Williamsburg. The successor to Dr. John M. Henderson will be chosen at the April meeting of the board.—Dr. John W. Williams, Richmond, who has been seriously ill with influenza is convalescent.—Dr. Truman A. Parker, Richmond has been appointed surgeon of the Seventieth Virginia Infantry with the rank of major.

Jamestown Exposition.—Dr. Moses Benneche, Norfolk is in charge of the medical exhibit at the Jamestown Exposition. A demonstration of the methods for the prevention and cure of tuberculosis will occupy 5,000 square feet of space. Dr. Benneche expects to go to Europe in the interest of the exhibit.—Major Charles A. Woodruff, surgeon U. S. Army has been appointed chief surgeon and chief sanitary officer of the troops of the United States troops and militia to be employed at the Jamestown Tercentennial Exposition.

WASHINGTON

Personal—Dr B F Roller, Seattle, has been dangerously ill with septicemia—Dr Sarah J Dean, Seattle, was thrown from her carriage in a collision with a street car recently, and severely bruised

Epidemic Diseases.—At Quilcene 52 cases of trachoma are reported, and the public schools of the place have been closed and thoroughly fumigated—Spinal meningitis is reported to have broken out in the Puget Sound Navy Yard, Bremerton, and on the training ship *Philadelphia* at that place The yard is under quarantine—At Toppenish 5 cases of small pox are reported and 17 individuals are under quarantine

WISCONSIN

Epidemic Diseases.—Viroqua reports 20 cases of smallpox—Eau Claire has four cases of smallpox of a mild type—Dr Gerhard A Bading, health officer of Milwaukee, recently went to Campbellsport to investigate 13 cases supposed to be smallpox—Several schools in Outagamie County have been closed on account of an epidemic of measles—Typhoid fever is reported to be prevalent in Manitowoc

Society Meetings.—At the annual election of the Barron Polk Rusk County Medical Society held at Rice Lake, the following officers were elected President, Dr William B Hopkins, Cumberland, vice presidents—for Barron County, Dr Grant F Tanner, Turtle Lake, for Polk County, Dr Abraham L Wells, Clear Lake, for Rusk County, Dr Lambert M Lundmark, Ladysmith, and secretary, Dr Olaf M Sattre, Rice Lake—At a meeting of the Outagamie County Medical Society, held at Appleton, Dr William N Nolan, Kaukauna, was elected president, Dr Henry W Abraham, Appleton, vice president, Dr Manly J Sandborn, Appleton, secretary treasurer, Dr William A Shepherd, Seymour, delegate to the state society, and Dr William E Zilisch, Hortonville, alternate

GENERAL

Measles on Battleship—It is reported that measles is epidemic on the battleship *Georgia*, and that more than 50 men from that ship have been transferred to the naval hospital, Portsmouth, Va

Medical Congress.—The second National Medical Congress of Mexico will be held in Mexico City, May 28-31, under the auspices of the Medical Society Pedro Escobedo The governors of the various states will send delegates to this congress, the work of which will be divided into eleven sections

Epidemics.—It is reported that an epidemic exists at Reynosa, Mexico, from which 100 deaths have resulted The governor of the State of Tamaulipas, however, denies that an epidemic exists—The milk supply of Havana and surrounding towns is said to be the cause of a reported epidemic of typhoid fever

Personal.—Passed Assistant Surgeon W W King of the Public Health and Marine Hospital Service has returned to the Bitter Root Valley of Montana to continue his studies of Rocky Mountain spotted fever—Dr John N Thomas, who has been in charge of the Mississippi River Quarantine Station a number of years, is reported to have been offered the position of medical inspector of Central American fruit ports during the quarantine season—Surgeon General Robert M O'Reilly is one of the American delegates to the International Red Cross Congress, which will open in London June 10

Accident Insurance Examiners Organize.—About 30 physicians and surgeons, connected with the examination work of accident insurance companies and claim departments met in Boston March 22, to discuss the plans for the formation of an organization A committee was appointed to draw up a constitution and by laws, to report at the next meeting, to be held April 8 The meeting was called at the instance of Dr Frank E Allard who stated that the object of the association is to protect the public and companies from frauds The committee appointed includes Dr Frank E Allard, chairman and Drs Edward M Greene, Francis D Donoghue, Harry H Hartung, Charles T Cutting and Charles O Kepler, all of Boston

Vienna Anglo American Medical Association.—This organization was founded Feb 4 1906 and is similar to the Anglo American Medical Association of Berlin which was described in THE JOURNAL, Jan 5 1907 page 65 The society met at first twice a month but meetings are now held every Friday evening addresses are given by prominent physicians All physicians of good standing irrespective of nationality, engaged in graduate work are eligible to membership The purposes of the society are to promote the social intercourse of its members to furnish information for the early and rapid

orientation of new members in regard to board and lodging restaurants and the scope and relative value of courses, and furthermore, to promote the scientific advancement of its members The membership of the association averages from 80 to 100 the entire year The control of the personnel of certain popular courses has been placed in the hands of the association in order to enable the society to place the rights of priority to enter these courses on the fairest possible basis, namely, the length of time the applicants for admission have been in Vienna For this privilege the association assumes, in a measure, the responsibility for keeping the courses full and for conducting them to the advantage also of the men who give them A study of the register of the association shows an increase in the number of American physicians studying in Vienna During 1904 210 physicians attended the various special courses and clinics, in 1905, 218, and in 1906, 295 In January and February of this year 55 men registered from various parts of the United States, as follows New York, 9, Ohio, 7, California, 8, Pennsylvania, 6, Illinois, 6, Washington, 2, Nebraska, 1, Oregon, 2, Texas, 1, Connecticut, 2, Iowa, 1, Tennessee, 1, Montana, 1, Michigan, 2, Maryland, 1, Kentucky, 2, Virginia, 1, New Hampshire, 1, Massachusetts, 1

CANADA.

University News.—The chair of medicine and clinical medicine in McGill University, Montreal, which was left vacant by the recent death of Dr James Stewart, has been filled by the appointment of Dr Frederick G Finley for the didactic work and of Dr Henri A Lafleur and Charles F Martin to have joint charge of the clinical work

Medical Inspection Stopped.—The medical inspection of schools in Montreal has been stopped for the present, owing to lack of sufficient funds to pay the 40 medical inspectors Since the inspection began, six months ago, there is said to have been 70 per cent less disease and uncleanness in the schools of Montreal than formerly

Militia Medical Officers Appointed.—The following senior medical officers have recently been appointed in the Canadian militia Eastern Ontario, Drs William A Willoughby, Colborne, Richard W Garrett, Kingston, and J A McCammon, Quebec command, Drs Henri Trudel, St. Gregoire, J P Lord, Joseph E Grondin, Charlesbourg, Ernest R. Brown, Montreal, and P Ostigny

Ministry of Health.—Dr Domingo Ornanos, Mexico City, president of the American Public Health Association, has appointed the following as a special committee to further the establishment of a ministry of health in Canada Dr Robert M Simpson, chairman of the Winnipeg Board of Health, Dr P H Bryce, chief medical officer of the Department of the Interior, Ottawa, and Dr F Montzambert, director general of public health for Canada

Hospital News.—An addition is to be erected to the Stratford (Ont.) General Hospital at a cost of \$20,000 It will provide for children's wards, maternity wards and operating room—Nurses' homes are to be erected in connection with the Western Hospital, Montreal, and the Royal Victoria Jubilee Hospital, Victoria, B C—The Toronto Provincial Hospital for the Insane, following the appointment of a resident pathologist has commenced the publication of a regular monthly bulletin on psychiatry This marks a distinct advance in the study of psychiatry in Ontario The first volume is largely devoted to methods of examination and to paranoias—The thirty-fifth annual report of the British Columbia Provincial Hospital for the Insane shows that 150 patients were admitted to that institution during 1906, being 27 more than the previous year Of this number 108 were males and 42 females During the year 79 patients were discharged, the largest number in a single year

FOREIGN

Flowers and Plants for Berlin Hospitals.—A flower show was held at Berlin in March to raise funds to keep the public hospitals constantly supplied with cut flowers and plants

Metric System Rejected by Great Britain.—The British Parliament has rejected, by a vote of 160 to 118, a proposal to make the metric system standard in the United Kingdom

German Medical School Founded in China.—Shanghai is to have a German medical school and Claude du Bois Reymond of Berlin has been appointed professor He is the son of the famous physiologist and has devoted himself mostly to ophthalmology

Recipients of Salomonsohn Prize.—From the endowment for promotion of scientific research known as the Salomonsohn foundation sums have been given recently to Madam Rahmo

witsch Kempner of Berlin, Rosenfeld of Breslau and Zoeppritz of Göttingen, about \$500 being divided between them

Free Tuberculosis Dispensary in Constantinople—An anti tuberculosis league in Constantinople will open a free dispensary where people, irrespective of creed and nationality, may receive treatment for tuberculosis or any other disease of the respiratory organs. It will be conducted as are similar institutions in western Europe

Typhoid Fever in Turkey—The *Lancet* states that there is much typhoid fever in several suburbs of Constantinople. In Haskeuy, on the left bank of the Golden Horn, more than 90 cases have been reported in a comparatively short space of time. The sanitary authorities are alarmed and the prefect of the city has ordered that all the drains and fountains should be examined and necessary repairs made

Transactions of the International Cancer Conference—A special number of the *Zeitschrift f. Krebsforschung* is devoted to the transactions of the international conference of workers in cancer research which was held at Heidelberg last September. The journal in question is issued by D. v. Hansemann and G. Meyer as the official organ of the German cancer research committee, which has its central office in Berlin, Bendlerstrasse 13

Extensive Bovine Vaccination in Argentina—P. Römer of Marburg leaves at once for Buenos Ayres to apply von Behring's method of vaccination of cattle against tuberculosis on an extensive scale on request of the Argentine government. Römer has been at the head of one department of von Behring's Institute for Hygiene and Experimental Therapy, and the German government conferred the honorary title of professor on him as he left for South America

Ernst Haeckel's Fiftieth Professional Anniversary—On the occasion of the fiftieth anniversary of his graduation in medicine, Prof. Ernst Haeckel of Jena was made a privy medical counselor with the title of *Excellenz*. He practiced medicine for a time in Berlin, but then turned his attention entirely to the natural sciences and made his name famous with his researches and publications on comparative embryology, anatomy and physiology. He is now in his seventy third year and said to be in the best of health

Resignation of Hospital Medical Staff at Cracow—A Vienna exchange states that the physicians connected with the public hospital at Cracow recently petitioned the authorities for increased remuneration. Their request was denied and they have unanimously decided to resign their positions on April 1, their resignations to take effect in two weeks. Steps are being taken to insure that their action will be sustained by physicians generally throughout Austrian Poland, so that no physician will accept a position in the hospital under present conditions

Recipients of Tiedemann Prize—This prize is awarded every fourth year by the Senckenberg Society at Frankfurt a. M. to the German writer who has produced the best work along the lines of comparative anatomy and physiology. It was awarded this year to E. Buchner of Berlin for his research which has demonstrated that the process of fermentation is not due to the action of living organisms, but is a physical contact action. The previous recipients of the prize have been Koch, Ehrlich, Bütschli, E. Fischer, von Behring, A. Kossel and F. Schaudinn

A New Maternity for Constantinople—The Italian Hospital of Constantinople, according to the *Lancet*, has opened a maternity section for the poorer classes of the population under the charge of Dr. Stavridis. Three days a week there are free consultations. If a woman desires to enter the hospital she must write her name in the register kept at the hospital for that purpose and occupy the bed assigned to her. If a woman desires to be delivered in her own home she will be furnished information and assistance. The rooms in the maternity are equipped with every modern appliance, and the institution should prove a boon to indigent mothers

Death of Berthelot, Founder of Organic Synthesis—The death is reported from Paris of another great chemist, Prof. M. P. E. Berthelot, at the age of 80, to whom is ascribed the honor of laying the foundations for organic synthesis and for thermochemistry. Besides his important pioneer work in these lines he published many articles on other phases of chemical research, fully 600 works issuing from his pen. The list includes a number of historical treatises on chemistry and alchemy, the results of study of papyrus and of Greek, Arabian and Syrian records. He took an active part in public life, serving as minister of foreign affairs and as senator, and his long life was crowned with honors, although he never sought to make a pecuniary profit out of any of his important scientific

discoveries from which others are still reaping such harvests

Blackwater Fever in Bengal and Assam—Blackwater fever is reported to be more virulent than ever in Jalpaiguri and the tea planters have appealed to the lieutenant governor of Eastern Bengal and Assam for help. During 1906, 13 young Europeans out of a population of 200 died from this disease, and the survivors are beginning to ask themselves if the worldly prospects are such as to justify them in running so serious a risk to life by remaining there. According to the *British Medical Journal*, the mortality is not confined to Europeans, that of the coolies and of all whose work lies in the Duars is appalling, and it is hoped that the government will appoint a commission to investigate the matter. In spite of all that has been done on the subject, it is felt that the knowledge of blackwater fever is in an unsatisfactory condition and it appears that in Jalpaiguri the conditions for studying the subject are favorable. There are physicians on the spot who have intimate knowledge of the clinical features of the disease and of the local conditions and who will gladly place these valuable assets at the disposal of any commission which the government may appoint. The planters have promised a considerable sum toward the expense of an investigation, and as the existence of an important industry is at stake the government can hardly fail to help in the matter

Congresses in Europe This Year—The International Congress for Psychiatry, Neurology, Psychology and the Cure of the Insane will be held at Amsterdam, September 2 to 7.—It will be followed a week later by the first congress of German neurologists, which meets at Dresden. At the latter the main addresses are to be on various phases of the surgical treatment of nervous affections, delivered by Krause, Bruns, Neisser and Müller.—The congress of French speaking neurologists and alienists is to be held in Switzerland in August, Prévost at Geneva to preside. Professor Berdez of Lausanne is the secretary. The subjects to be discussed are hysteria, periodical neuroses, medicolegal testimony and responsibility.—The Seventy ninth Congress of German Physicians and Scientists—the *Naturforscher* congress—opens at Dresden September 15 and closes the day before the congress of hygiene at Berlin.—The Second International Physiotherapy Congress will convene at Rome in October. The Italian congresses also meet in October as a rule, and the French surgical congress at Paris.—The Seventh International Physiology Congress will meet at Heidelberg August 13-16, and the International Anti-tuberculosis Conference at Vienna September 19-21 followed October 2-5 by the first annual congress of German speaking urologists.—The Twelfth German Gynecologic Congress will be held at Dresden May 21-25. Leopold will preside, Weindler of Dresden is the secretary. The principal subjects are pelvic enlarging operations, and sepsis in gynecologic operations.—Elaborate preparations have been made for the Fourteenth International Congress of Hygiene and Demography at Berlin, September 23-27. The chief of the imperial board of health, Professor Bumm, will preside. Further particulars can be obtained from the secretary, Dr. Nietner, Liebhornstrasse 9, Berlin W. 9

LONDON LETTER

(From Our Regular Correspondent)

LONDON, March 16, 1907

A Central Emergency Fund for Maintaining the Interests of the Profession

As the British Medical Association is constituted as a "limited liability company" not formed for profit no part of its funds can legally be used for the benefit of any individual member except by way of remuneration for services rendered to the association. This has prevented the giving of financial assistance to its members engaged in disputes with organized bodies in the matter of contract practice. The council therefore has instituted for this purpose the central emergency fund, which is maintained by voluntary subscriptions. All members of the profession are invited to contribute. Any contribution may be marked for use in specified disputes or for application to special methods of carrying out the objects of the fund. The fund will be under the control of the medico-political committee of the association.

Lord Lister's Eightieth Birthday

Lord Lister's eightieth birthday falls on April 4, 1907. A movement has been started to convey to him the tribute which is felt for his work. Dr. C. J. Martin, director of the Lister Institute, has suggested that the Lister Institute expression could take a noble pulse in the future. His scientific papers, prefaced by a list of his discoveries of the anti-septic

London Ambulance Commission

The first meeting of the London Ambulance Commission was held February 14. An experimental motor car, at a cost of \$2,500, has been made and a station will probably be built near St Bartholomew's Hospital. This ambulance is equipped with every latest portable appliance for surgery, together with a full stock of medicines, lotions and bandages. A surgeon will accompany the ambulance. It seems strange that the largest and richest city of the world should have only just awakened to the fact that her ambulance arrangements are many years behind the times. Hand ambulances and stretchers are still in vogue in London, but a beginning has been made, and this state of affairs will soon be changed.

LONDON, March 22, 1907

The Royal Commission on Tuberculosis

An important report on the histologic and bacteriologic investigations carried on by Dr Eastwood in connection with the Royal Commission on Tuberculosis has just been issued. It emphasizes the findings previously referred to in THE JOURNAL—that bovine tuberculosis is transferable to man. But Dr Eastwood adds the interesting statement that "The evidence before him confirms the view that some viruses of human origin are relatively innocuous to bovines." Bacilli of bovine origin produce in bovines lesions of a highly acute type. Some viruses of human origin produced similar results, while others produced only a mild type of disease. In the anthropoid ape the human viruses, which were relatively innocuous to bovines, produced typical tuberculous lesions similar to those produced by bovine bacilli. Even in small doses bovine bacilli produced typical tuberculosis. Dr Eastwood concludes that his investigations have failed to give the slightest indication that there is any peculiarity about bovine viruses which might suggest that compared with other viruses they are relatively innocuous to man.

Death of a Surgeon from an Accident During an Operation

While operating for appendicitis, Dr Lawson of Hull pricked his finger in November, 1906. For several weeks he lay seriously ill with septic cellulitis. After a few weeks' vacation he returned to work, but in impaired health. Toward the end of January he was taken ill with pleurisy, which terminated in empyema. He came to London, where his chest was opened and drained, but his reserve strength was reduced so low that he lingered for a few weeks and died March 15, at the age of 56. Many years ago he also suffered in the discharge of his duty. He contracted diphtheria from sucking a blocked tracheotomy tube and saved the patient's life, for which he was awarded the Albert medal. The result of that accident was to render him unfit for work for a year. His reputation as an operator was considerable. He appears to have been the first to perform the operation of pneumonectomy. In cases of early phthisis he removed the affected portion of lung with success.

The Society of Tropical Medicine and Hygiene

A society of this name has been founded. The determination to found it was formed two months ago at a meeting held at the Colonial Office on the suggestion of Mr James Cantlie. Sir Patrick Manson presided, and a subcommittee was formed to make the necessary arrangements, consisting of the chairman, Col Melville, Dr Sandwith, Dr Carnegie Brown, Prof Ronald Ross, Dr G. C. Low and Mr Cantlie. To these were added the following in order to constitute a general committee: Professor Nuttall (Cambridge), Dr W. Hartigan, Lieutenant Colonel Giles, Dr Sambon. The promoters hope that the society will become universal, and embrace every man and woman interested in tropical medicine. Nine-tenths of the members will probably live abroad, and the object will be to provide mutual instruction and support for all.

The Epidemic of Cerebrospinal Fever

Cases of cerebrospinal fever continue to be reported from London and various parts of the country, but epidemic prevalence is still confined to Glasgow and Belfast. In Glasgow on March 15 112 cases were under observation, as compared with 101 on March 8. On March 19 the health officers issued a statement that during the past two weeks there had been 93 cases and 55 deaths, as compared with 90 cases and 60 deaths in the preceding fortnight. During February, 140 deaths occurred in the eight principal towns of Scotland, being 60 more than in January. In Belfast 185 cases have been reported up to the present and 104 deaths. In Dublin 15 cases and 11 deaths have occurred, but no new case has been reported since March 6.

The Eighth International Conference of Red Cross Societies

The Eighth International Conference of Red Cross Societies will be held in London June 10-15. It is believed that the foreign guests will number 200—from all the European states, America, Japan, etc. They will probably be received by King Edward. Social entertainments are being organized by the Marchioness of Salisbury, Lord Rothschild and others.

"Thickening" in Cream.

Dr Collingridge, health officer of the city of London, refers in his monthly report to the pernicious practice of adding starch to cream. There is no legal definition of cream, and the fat present in various samples varies from 15 to 55 per cent. The public forms its opinion of the value of cream by the only standard available—its thickness. The addition of starch or gelatin gives a fictitious appearance of thickness. A very small addition of thickening material will compensate for the absence of a large amount of fat and allow an inferior article to be sold as cream. A departmental committee in 1901 reported that the artificial thickening of cream by the addition of gelatin or other substance should raise a presumption that the cream is not genuine. The sale of foods and drugs act of 1875 makes it an offense to sell any article of food to which any matter or ingredient not injurious to health has been added fraudulently to increase the bulk, weight or measure, or to conceal the quality.

VIENNA LETTER.

(From Our Regular Correspondent)

VIENNA, March 10, 1907

Professional Secrecy and the Present Law

In a lecture delivered before the medicolegal society, Dr Kienböck illustrated the false position in which the practitioner is placed by the law. Thus, the medical attendant is bound not to disclose the nature of the illness of his patient nor to give any particulars in regard to the condition of any one applying to him for professional help, while, on the other hand, the practitioner must inform the officers of an insurance company or of other corporations, who engage his services, of the health of certain individuals, thus violating the law. Furthermore, practitioners are bound to inform the police of every case of injury or suspicious disease, and to inform the magistrates of cases of infectious disease. Each one of these breaches of professional secrecy is, strictly speaking, amenable and involves danger to the doctor. On the other hand, the persons auxiliary to the doctor—nurses, servants, not qualified assistants—are not bound by law to keep the secrets of which they may obtain knowledge during their function in the service of the doctor. In cases of suits for fees, the doctor is not allowed to disclose to the court the nature of the disease of the patient although such a disclosure might mean for him a very substantial help in the litigation. Kienböck also spoke of the painful position of the practitioner, who by his office learns of dangerous conditions of his patients as, for instance, in cases of syphilis or tuberculosis of a bride or bridegroom, or of the deafness or blindness of a railroad employé, or of the mental condition of a business man suffering from cerebral paralysis. The lecturer demanded the adoption of a wider view of modern ethics in legislation and the addition of necessary provisions to the law now in force.

Jubilee of the Vienna "Opérateur-Institut"

The "surgeon's school," or "Opérateur-Institut," of Vienna recently celebrated its centennial anniversary. It was founded by Emperor Francis I, who, acting on the suggestion of the then famous professor of surgery, Dr V. v. Kern, ordered him to teach several well qualified surgeons in a special ward and he, the emperor, would defray the expenses. This institution was then incorporated in the University of Vienna, and in 1803 the two surgical clinics were ordered to take the "Opérateur-Institut" over. Since then, every surgeon, who desired any special instruction in his branch, had to become a pupil of this school, admission was not easy, as a severe examination in anatomy and surgery had to be passed before obtaining permission to enter the clinic. It may be stated that every living well qualified surgeon in Austria has been a pupil of this school. All the regular professors of surgery in the Vienna university have been directors or teachers in the institute, so that there is always first class instruction, while the clinical material to be drawn on numbers upward of 25,000 patients for both clinics. The centennial celebration was described in these columns on page 1043.

Pharmacology

GUDE'S PEPTO MANGAN

An Investigation Into the Reliability of an Alleged Scientific Report.

In THE JOURNAL, Sept. 23, 1905, we exposed the misuse, by the exploiters of Pepto Mangan, of the government report on anemia in Porto Rico. The conclusion of the Government Commission, which investigated the anemia prevalent in Porto Rico, was that iron was of subsidiary importance in treatment, and that the carbonate, as represented by Bland's pills, seemed to give the best results. Immediately Messrs. M. J. Breitenbach & Co. used this report to exploit their preparation (Pepto Mangan)—first in advertisements and reading notices and later in a garbled extract of the report printed in pamphlet form and scattered broadcast among physicians. This pamphlet conveyed the idea that Pepto Mangan had been endorsed by the government as superior to any other iron preparation, and that it had proved most efficacious in the treatment of anemia, that "this report alone would suffice to establish Pepto Mangan at once as the foremost hematonic

known." The Commission later published a denial stating that Pepto Mangan was used by them only for a little while because it was found to be of even less value than other iron preparations.

Some months ago another pamphlet was sent out by the same company purporting to give the results of the treatment of 32 cases of "infantile anemia" at the Infants' Hospital, Randall's Island, New York City. The report was written by Mateo M. Guillen, designated as house physician and surgeon. A cursory examination of this pamphlet showed that five of the 32 cases cited had an initial blood count of over 4,500,000 erythrocytes, and one over 70 per cent hemoglobin, with nearly 4,000,000 reds. Thus 18 per cent of the cases cited could not be classified as anemia. Moreover, in 26 cases the anemia had followed some acute disease or the patients were convalescent from such a disease. In either case, spontaneous improvement was naturally to be expected.

THE UNRELIABLE REPORT

These facts aroused suspicion and suggested further investigation. Accordingly, we had the books of the ho-pital inspected by a competent representative, who devoted consid-

The above table is reproduced from a sheet 11 by 14 1/2 inches which is a part of the pamphlet "On the Treatment of Infantile Anemia" following in display headline. Comparative table of 32 cases of Infantile Anemia treated at the City Infant Hospital, Randall's Island, New York City during a period of four months with Gude's Pepto Mangan. By Dr. Mateo M. Guillen, M.D., House Physician and Surgeon.

erable time to a careful examination of the original records of the hospital. His report follows:

"In reply to your request that I examine into the authenticity of the cases advertised as having been treated with Pepto Mangan at the City Hospital, Randall's Island, I am able to make the following report, after a thorough examination of the records of the hospital in the clerk's office, the daily charts and the physicians' order books.

"Dr. Mateo M. Guillen, house physician in 1902, whose name is attached to the report as having treated the cases with Pepto Mangan, has been in South America since that time. Through the kindness of Dr. William L. Stowell, visiting physician at the Infants' Hospital, I was furnished with the full names and data of the patients whose cases are reported, so I was able to get the correct histories of them in the hospital records. Dr. Stowell informed me that he was aware that some of the patients had received Pepto Mangan simply as one form of iron, though he believed the simpler forms of iron preferable, and that if I would trace the treatment in the cases I would doubtless find the simpler forms of iron prescribed.

"Examination of the hospital records and daily charts of the cases show remarkable discrepancies from the results and treatment as advertised in the Pepto Mangan pamphlet. Some of the most striking are the following:

"Three patients, reported in the pamphlet as cured through the use of Pepto Mangan, the hospital records show died, viz.

"Case II, K. T. (Katie Turner)

"Case XIX, W. B. (William Barkdale)

"Case XXII, R. S. (Reuben Schehr)

"The results in all the cases are advertised as being obtained by Pepto Mangan. On the contrary, the daily charts and the doctor's order books show that some of the patients never received Pepto Mangan. For instance, in Case XII, L. C. (Lillian Codney), instead of Pepto Mangan, was given *syrupus ferri iodidi*, and at other times malt zyme and liquid peptonoids and various local, external and symptomatic medicines, but at no time was Pepto Mangan prescribed.

"Similarly, in Case XIII, I. H. (Irene Harowitz) was never given Pepto Mangan.

"The charts of Case IV, C. V. (Catherine Vaughn) show that Pepto Mangan was only prescribed once, and at other times she was given *syrupus ferri iodidi*.

"Similarly, the charts of Case V, H. V. (Helen Vaughn) show that Pepto Mangan was only prescribed once, and at other times was given *syrupus ferri iodidi*.

"In Case XVIII, W. B. (William Born) was given Pepto Mangan on July 19, but it was discontinued on August 13, although the pamphlet states that he was under treatment fifteen weeks.

"In Case X, D. S. (David Smulewitz) was given syrup of hypophosphites and cod liver oil along with the Pepto Mangan.

"I was informed by Dr. Oberdorfer, who was on the hospital staff at the same time, that in Case I, E. P. (Eva Pases), though Pepto Mangan was given, arsenic was pushed in very large doses.

"Of the thirty-two cases reported in the Pepto Mangan pamphlet, only twenty-two were reported by Dr. Stowell, and among the history charts for that period I was unable to find any cases corresponding to the initials of the additional ten cases.

"I hereby swear that the above statements are correct data taken from the records of the City Infants' Hospital, Randall's Island, and am able at any time to prove them by the mentioned records.

"GEORGE M. GELSER."

[Mr. Gelser is a senior student in the medical department of Cornell University.]

SUMMARY

This throws a somewhat different light on the impressive report of thirty-two cases. Analysing the results obtained, we find that 13 cases, namely, Cases VII, XV, XXI, and all of the cases from XXIII to XXXII were not found on the hospital records. The table in the pamphlet shows that the patient in Case V died. The hospital records show that Patients II, XIX and XXII, which were reported as cured, also died. The records also show that in Cases XII and XIII Pepto Mangan was never given; that in Cases IV and V but a single dose was given; that in Cases I and X this prepara-

tion was given in conjunction with other preparations, such as syrup of hypophosphites and iron, cod liver oil, etc., which can certainly claim a share in the results. In Case XVIII, in which the report says Pepto Mangan was given for fifteen weeks, the records show that it was given but three weeks and a half. Cases XIII, XV and XVII are not cases of anemia at all. Striking these from the table, we have left eight cases entered on the hospital records, in which there is evidence that Gude's Pepto Mangan was administered. But the table itself shows that seven of them, namely, Cases III, VI, VIII, IX, XI, XIV and XX, were entered as convalescent at the time of beginning treatment, the anemia following some acute disease, such as pneumonia, whooping cough, bronchopneumonia, enterocolitis and summer diarrhea. In all of these cases, anemia is to be expected during the height of the disease, and rapid recovery from the anemia, as soon as convalescence is established, would also be observed in 95 per cent of all cases which received ordinary care and nourishment, regardless of medication. The imposing and delusive chart which has, on first sight, such an ultra scientific appearance, melts down under impartial investigation to a single case which is in any sense worthy of consideration. Case XVI is reported as that of a child, 22 months old, suffering from anemia, accompanying acute tubercular epiphysitis. In this case, Pepto Mangan was given for nine weeks. An increase of red blood corpuscles from 2,904,000 to 3,872,222, and an increase of hemoglobin from 40 to 64 per cent took place in the same period. Even the sanguine and optimistic author of the pamphlet and the compiler of the chart does not venture to record this case as anything more than improved.

PREVALENT DISREGARD OF TRUTH

Two things may be learned from this interesting analysis. The first is that so-called scientific reports are only of value in proportion to the veracity and reliability of the writer. Unless the statements of the author are founded on scientifically established facts, they are delusive and as dangerous as the false lights of a shipwrecker or the decoy signals of a train robber. It seems incredible that any physician having the slightest conception of the dignity and honor of the profession would deliberately falsify and distort hospital records for the sake of the pittance offered by proprietary houses, whose preparations he lauds, or for the sake of the cheap notoriety which he obtains while lending his name to such a deception.

The second and equally deplorable fact is that firms composed of men who are personally honorable seek to obtain business by means of such unjustifiable methods. It might be said in defense that the M. J. Breitenbach Company did not investigate the statements set forth in the pamphlet, and that it relied on the truthfulness of the writer. This does not relieve the firm of its responsibility.

There is an apparent tendency on the part of proprietary houses to accept any report, statement or testimonial, no matter how obviously absurd, distorted or highly colored—if only it be favorable to their preparations—and to eliminate and to suppress any unfavorable reports or facts. This tendency has helped to produce the present deplorable conditions in the proprietary medicine business. Such methods are not scientific, they are not even in accord with the ordinary principles of business honesty, which are supposed to obtain among reputable merchants. An honorable and legitimate business should have a better foundation than advertising matter which will not stand investigation.

Lactopeptine Exposed Thirty Years Ago

SOUTH BEND IND. March 23 1907

To the Editor.—The report on Lactopeptine in THE JOURNAL of March 23 is very interesting and it is hoped that it will prove equally instructive to your readers. While it is interesting to us pharmacists I can not say it is especially instructive, for the facts contained therein have been surmised if not actually known to pharmacists for many years. The surprising thing however is that the members of the medical profession should go along blindly prescribing such preparations year after year, often against our protest, as was more espe-

cially the case with the acetanilid mixtures. For years the pharmaceutical journals had pointed out the deception concerned in the exploitation of the medical profession (and eventually of the public) by nostrums of this character with out avail, until the Council, through *THE JOURNAL*, began some two years ago, to show up the true character of these nostrums. Lactopeptine and especially its elixir have been used in enormous quantities by the medical profession, although in 1876, soon after its introduction, Prof. Emil Schaffer of Louisville, Ky., contributed a paper to the American Pharmaceutical Association, in which he reported some experiments he made on Lactopeptine, and proved that it had no greater digestive value than the saccharated pepsin then in vogue. This paper appeared in the Transactions of the American Pharmaceutical Association for 1876. Although Schaffer was an authority on the subject, he being the author of the first process for obtaining pepsin in a pure state, it is not apparent that any attention was paid to this article by the medical profession, in fact, it was entirely ignored by medical journals, and extensive advertising soon made Lactopeptine the most extensively employed proprietary article. This leads to the observation how helpless we pharmacists have been in the past because of the lack of cooperation of the medical profession. We have had to supply such articles as were in demand, and when such articles as the Compound Powder of Acetanilid and the Compound Powder of Pepsin and its elixir in the Pharmacopoeia and National Formulary are criticised, such criticism should be directed against the members of the medical profession because of their lack of interest and cooperation in the preparation of these standard works. Now that their attention has been so forcibly directed to this anomalous condition, it is hoped that physicians will participate actively in the revision of these joint authoritative standards.

LEO ELIEL,

President, American Pharmaceutical Association

Book Notices

A TREATISE ON THE MOTOR APPARATUS OF THE EYES Embracing an Exposition of the Anomalies of the Ocular Adjustments and Their Treatment with the Anatomy and Physiology of the Muscles and Their Accessories. By G. T. Stevens, M.D., Ph.D. Illustrated with 184 engravings, some in colors. Cloth. Pp. 400. Price \$4.50 net. Philadelphia: F. A. Davis & Co. 1906.

This book is offered as a sequel to the author's work on "Functional Nervous Diseases," the preface stating that "difficulties of adjustments of the eyes are a source of nervous trouble, and more frequently than other conditions constitute a neuropathic tendency." The subject is very fully covered, beginning with a short historical sketch dealing with the time when actual strabismus only was recognized, and including our present recognition of heterophoria. The comparative anatomy of the eye muscles of fishes, birds, reptiles and mammals is considered in the chapter devoted to anatomy. This chapter is particularly exhaustive and is divided into ten sections, which deal with the movements and positions of the eyes, with comparative anatomy, with the orbital measurements, planes, axes, etc., with the eye-muscles themselves, and with the insertions of the tendons, etc., covering the anatomy of the orbital aponeuroses, capsule of Tenon, vessels and nerves. Under physiology is discussed the subject of binocular vision, with the various methods of detecting and encouraging its development. The remainder of the book is devoted to the study of the anomalous conditions of the motor apparatus of the eyes, consistent and inconsistent with the physiologic state. The illustrations are modest in character and number as compared with the average book of its day. As a whole, it offers a fair résumé of the important advances made by its author in muscle work during the past ten years, but neglects those ideas advanced by others.

WOMAN IN GIRLHOOD, WIFEHOOD, MOTHERHOOD. A Guide in the Maintenance of Her Own Health and that of Her Children. By M. Solis Cohen, A.B., M.D., Instructor in Physical Diagnosis, University of Pennsylvania. Illustrated with Color Plates, Scientific Drawings and Half-tone Engravings with Manikin Chart, printed in colors with an Index. Cloth. Pp. 469. Price \$2.00 net. Philadelphia: The John C. Winston Company.

As a book for the wife and mother and a guide to such domestic medicine as is really desirable, this work meets all requirements of clearness, simplicity of language, accuracy of statement, and temperate, judicious treatment of delicate subjects. While it gives helpful suggestions as to the preservation of health and as to action in emergencies, it discourages self-medication and especially the resort to "patent medicines." The work consists of three sections, general hygiene, and the rules for care of the body applying especially to women. The hygiene of the pregnant woman and the care of mother and child during confinement, and the hygienic care of children. The popular aim of the book requires the introduction of many topics which are only indirectly of medical interest, but these parts appear to have been written with judgment and care. Many illustrations are introduced, both of medical and artistic merit. The work appears to be one that the physician can cordially recommend to his patients, and deserves a place in every home.

PREVALENT DISEASES OF THE EYE. A Reference Handbook especially Adapted to the Needs of the General Practitioner and the Medical Student. By S. Theobald, M.D., Clinical Professor of Ophthalmology and Otology in the Johns Hopkins University etc. Cloth. Pp. 551. Price \$4.50 net. Philadelphia: W. B. Saunders Company. 1906.

This is the most comprehensive work yet written for the special benefit of the general practitioner. The book begins with a very complete synopsis of contents, a distinct advantage to the busy man who, by its aid, may read just what he needs with little expenditure of time. The question of diagnosis is given greatest space and prominence, as it should be. The family physician sees the eye cases first, and a knowledge of the more important diseases is essential to him in order that he may treat the simpler cases and send the severe ones to an ophthalmologist without delay. The line is definitely drawn, however, between those cases which can be cared for by the family physician and those requiring the services of a specialist, and the proper warning sounded. The more technical divisions of ophthalmology, such as the use of the ophthalmoscope, muscular anomalies, etc., are merely mentioned, as they require thorough study and preparation to be of definite value. The dominant note of the book is the completeness with which diagnostic methods are set forth in a style very clear and readable.

MODERN SURGICAL TECHNIC IN ITS RELATIONS AND WOUND TREATMENT. By C. J. Pearson, M.D., M.C., F.R.C.S., Professor of Surgery, Queen's College, Cork. Illustrated with Two Colored and Other Plates. Cloth. Pp. 392. Price \$3.50 net. New York: William Wood & Co.

The author has compiled in this work the subject matter of a series of lectures on the technical details of modern surgery. It is designed to meet the requirements of the students and assistants in surgery who are not familiar with the science of bacteriology and the prevention of wound infections. Its chapters are devoted to a clear and concise discussion of surgical bacteriology and infections. The mode of wound infection, the consequence of such infection and the various methods employed in the prevention of infections are treated in a consecutive and exhaustive manner. A chapter devoted to the preparation of ligature and suture material is especially complete and comprehensive. Some attention is given to operative technique including a discussion of surgical needles and their uses, together with a description of the various kinds of sutures.

TEXT BOOK OF THE PRACTICE OF MEDICINE. For Students and Practitioners. By Holbart Amory Hare, M.D., B.Sc., Lecturer of Therapeutics in the Jefferson Medical College, Philadelphia. Second Edition. Revised and enlarged with 171 engravings. Cloth. Pp. 1122. Price \$7.00 net. Philadelphia: Lea Bros. & Co. 1906.

That this work has met the needs of practitioners as well as medical students is sufficiently evidenced by the fact that a new edition has been called for in two years since the first appearance of the work. The book has been thoroughly revised the latest views that have been accepted in practice and clinically correct having been embodied in it. It is not yet established as facts have been established. The treatment of the subject as in the first edition is clear, concise and practical. The book is a valuable addition to the library of every practitioner.

GENITO URINARY DISEASES AND SYPHILIS By H. H. Morton M.D. Clinical Professor of Genito-Urinary Diseases in the Long Island College Hospital Genito Urinary Surgeon to the Long Island and Kings County Hospitals and the Polhemus Memorial Clinic. Illustrated with 158 half tones and photo engravings and 7 full page color plate. Second edition revised and enlarged. Cloth Pp 500 Price \$4.00 net Philadelphia F. A. Davis Company 1906

This work is admirably written, well arranged and well printed, and the author's ideas, which are those of the German school, are clearly set forth. The subject of gonorrhea is well covered, and the treatment of acute and chronic urethritis is explicitly dealt with. Recapitulations, which are frequent, could well have been sacrificed to the elaborations of the more important subjects. The author's advice in case one fails to find the urethra in doing an external urethrotomy without a guide, to blindly puncture with Guiteras' trocar in order to reach the limit of the canal behind the stricture, must surely be condemned as unwise, as the results might be unsatisfactory, not to say disastrous, if such procedure were followed by others than the expert operator. Neither can we agree with the statement that it is necessary to produce pytalism in order to cure syphilis, nor with the advice to curette the floor of a gummatous ulcer. Rather striking is the omission of some of the generally accepted remedies, viz Nitrate of silver and chromic acid solutions, often used as applications to mucous patches.

PRACTICE OF OBSTETRICS Designed for the Use of Students and Practitioners of Medicine. By J. C. Edgar Professor of Obstetrics and Clinical Midwifery in the Cornell University Medical College. Third edition revised. Cloth Pp 1071 Price, \$6.00 net. Philadelphia P. Blakiston's Son & Co 1906

The same classification has been followed in this as in the previous editions. The size of the book has been reduced 100 pages, but 140 new illustrations have been added. The following subjects have been rewritten: Development of embryo, fetus, fetal membranes and fetal structures, chorioepithelioma malignum, treatment of placenta prævia, toxæmia of pregnancy, etiology of eclampsia, ectopic gestation, treatment of pelvic deformity, morbidity of the puerperium, indications for the induction of abortion and premature labor, use of forceps, Cesarean section, vaginal Cesarean section, Porro operation, and complete and incomplete hysterectomy. New subjects added are: Appendicitis complicating pregnancy, tapeworm in pregnancy, fibroma moliseum gravidarum (illustration), hematoma of the vulva (illustration), lactation atrophy of the uterus and breasts, brachial birth paralysis, vaginal incision and drainage (illustration), new history charts for institution work. The illustrations are good and the schematic drawings which accompany many of them add greatly to their value.

A MANUAL OF NORMAL HISTOLOGY AND ORGANOGRAPHY By Charles Hill Ph.D. M.D. Illustrated Flexible Leather Pp 468 Price \$2.00 net. Philadelphia W. B. Saunders Company 1906

This manual presents the fundamentals of histology in a clear cut manner, but the evident intention of the author is that this book should be used as an aid in laboratory work and to prepare the student for more thorough study in the class room rather than as a text book. The arrangement of subjects is excellent, the central idea being to lead the student up gradually from the simple to the complex. Considerable space is devoted to the mouth, especially the teeth, thus making the book a valuable one for students of dentistry. The illustrations are numerous and well made. The book is to be commended.

OBSTETRICS Edited by J. B. De Lee A.M. M.D. Professor of Obstetrics Northwestern University Medical School with the Collaboration of D. Roehrer M.D. and H. M. Stowe M.D. Vol 5 of the Practical Medicine Series. Comprising Ten Volumes on the Years Progress in Medicine and Surgery Under the General Editorial Charge of G. P. Head M.D. Professor of Laryngology and Rhinology Chicago Post Graduate Medical School Series 1906. Cloth Pp 560 Chicago The Year Book Publishers 1906

This book reviews the progress in obstetrics during the past year. Little advance has been made in the scientific fields of obstetric research. Under 'Eclampsia' are considered the biologic theories of the origin of this condition, and attention is directed to Zweifel's announcement that lacticaciduria is an important etiologic factor. The work as a whole, however, deals with the practical side of obstetrics.

Suggestions for Authors

In the midst of his exile for research on syphilis in monkeys in Java, Neisser has found time to voice his exasperation at certain habits of medical authors and to beg them to refrain. He has written an open letter on the subject which he sent simultaneously to the principal medical journals of Germany and which appeared in most of them about March 12. It is noteworthy that Neisser does not write from the standpoint of an editor, but merely from that of an earnest seeker for what is really important in current medical literature.

He appeals to medical writers to make the titles of their articles more concrete and thus give readers an idea as to the writer's views on the subject discussed. "For instance," he says, "instead of the title, 'Calomel Salve in Prevention of Syphilis,' write, 'Efficacy' or 'Non efficacy of Calomel Salve,' etc., instead of 'Administration of Mercury by the Rectum,' write, 'Inefficacy of Rectal Mercurial Treatment,' instead of 'A New Remedy for Gonorrhea,' why not name the remedy and state at the same time whether the writer's experience with it has been favorable or the reverse." "The worst of all titles," he adds, "are those such as 'Therapeutic Notes,' 'Clinical Experiences,' and the titles in which an affection is called by a new name without reference to the name under which it has previously been recorded." He cites as an example of the latter "Tuberculosis cutis pruriginosa," remarking how much better it would have been to have written, "Tuberculosis cutis pruriginosa, the so called Urticaria perstans." "One glance at the title would have then informed the reader—and likewise the larger multitude of non readers—exactly what the author was aiming at. Even those most interested in a subject are unable to read all the periodicals, the archives and journals, weeklies and monthlies, centralblatts and year books, all the time, but when they have occasion to read up on any special subject they are grateful, indeed, to those who make their sifting of the literature as easy as possible for them. The best way to do this is to make the titles of the articles a reflection in condensed form of their actual concrete contents, not a vague generalization." The titles need not be any longer, as a rule. He commends heartily the habit of appending a good summary of the article, adding that if authors omit this they can not complain if their communications fail to attract the attention they deserve.

He also expresses dissatisfaction with the articles printed without paragraphs or headlines. This he finds very often in English works, and he says that it makes the reading of the articles very difficult for him, adding that frequent paragraphs, numbering or lettering the different parts of the article, and the occasional use of black letter type would make it much easier to read the article and to discern the drift of the author's ideas, even when hastily scanning the article. Those works will be read the most eagerly and the most frequently which realize some of the above suggestions.

In conclusion he expresses his abhorrence of the footnotes which say merely *loc. citato*, in the place before cited, requiring long and weary search, perhaps, for the original citation. He continues "Some authors add a bibliography without citing names or without references to the titles in the text, so that such a tail piece, parading as an evidence of the literary and collecting industry of the author (or of some one paid for looking up the references) is absolutely useless to any one. A bibliography is valuable only as it saves future readers the trouble of hunting up the references. Consequently, the contents of each work cited should be indicated in some way. This might be done by adding a brief summary of the article to each title or by grouping them according to the phases of the subject. Quoting rare and practically inaccessible periodicals, transactions and the like, has scarcely more than decorative value. At least, they should be accompanied by the indication of some accessible periodical in which an abstract of the article cited can be found."

Physicians and Their Profession.

Under the above title the Trenton (N J) American comments editorially as follows

"There are few professional men so habitually misunderstood as physicians. The clergy are expected to practice self effacement, to work unselfishly for others, to be constant in good works, hoping only for a future reward. But the bodily physician oftentimes vies with the physician of souls in his loving kindness and self sacrifices, yet his acts are usually rewarded with suspicion.

"Popular ignorance is responsible for quackery in religion and in medicine. There are hosts of charlatans pretending to be able to cure souls of sin for a price, and there are quite as many who, for a similar consideration, promise to cure bodily ailments. If people would only take the trouble to learn something of religion and something of medicine, they would escape impostors in both of these professions.

"The health of a community depends largely on its information regarding the laws of Nature. Epidemics are in variably products of ignorance. Disease is the result of natural causes. The medical profession has sought out and is seeking out these causes. It alone can not remove them, but the intelligent action of the people can remove many of them.

"It has long been a practice of the Christian churches to send missionaries abroad to open a way for the establishment of churches and the advancement of religion. The American Medical Association has undertaken a similar missionary work, and Dr J N McCormack of Kentucky is touring the country for the enlightenment of many on the subject of medicine and its practitioners. His mission is to inform the ignorant of the possibilities and limitations of medicine and how to avoid calling the doctor. A strange mission for one whose living depends on his patients? Yes if the practice of medicine is regarded as a mere money making agency. But not at all strange if one is large enough to believe that all men are not sordid seekers after material gain."

More Societies Agree on Insurance Fees

Dr J Meigs of Lowell Mass, reports that the Middlesex North District Medical Society voted at its last meeting that a minimum fee of \$5 for life insurance examinations be adopted. The Androscoggin County (Maine) Medical Association and the St Louis County (Minn) Medical Society have taken similar action.

The Southern District (N D) Medical Society and the Van Buren County (Iowa) Medical Society have adopted the Kentucky resolutions.

Legislation Notes

Dr J V Stevens, secretary of the Wisconsin Board of Medical Examiners, has sent out a circular letter to the 60 county secretaries in his state, emphasizing the importance of cooperation between the state board and the county and state medical societies. Dr Stevens says

"Our board greatly appreciates the active and valuable assistance rendered by the county medical societies, in helping us to get rid of the medical quacks and impostors who have infested our state and robbed its citizens so long. We want to enlist every member in the state in an active campaign to aid us in securing the passage of bills now pending in the state legislature, introduced for the purpose of improving the standing of the profession, and in defeating the bills introduced by the quacks themselves in an endeavor to weaken and destroy the effectiveness of the laws we now possess."

One of the most promising features of society activity since reorganization is the effectiveness of cooperation between state boards and the organized profession. Where there is complete cooperation and unanimity between these two forces results otherwise impossible can be obtained.

It is reported that the New York County Medical Society has asked for the passage of a bill to protect reputable physicians who may be called in consultation in cases in which criminal operations have been or may be later performed. The law in New York state provides that any physician known to be present when an illegal operation is performed or who may be found treating a patient after such operation, is liable to arrest, fine and imprisonment. An instance recently occurred in which a physician, a member of the New York County Medical Society, was called in consultation

criminal operation had been performed. On investigating the law he found that he was equally liable with the physician who had performed the operation. It is reported that steps will be taken to amend the law so as to relieve physicians of responsibility and liability in case they are innocently called in as consultants.

The standing committee on tuberculosis of the Medical Society of the State of Alabama has issued a pamphlet and address to the members of the state legislature, setting forth the position of the profession regarding the control and suppression of tuberculosis in that state. The pamphlet explains the most recent views on the subject and points out the manner in which, through proper legislation, the citizens of the state may be protected from this disease.

The physicians of Shelbyville Ill have sent to the legislative committee of the Illinois State Medical Society a resolution protesting against the passage of senate bill No 21, introduced by Senator Chaffee, whose home is in Shelbyville regulating the practice of osteopathy in Illinois. A protest is made against the passage of the bill and the legislative committee is urged to use every means in its power to prevent the bill from becoming a law.

Queries and Minor Notes

SWEET BREATH IN INFECTIOUS DISEASES

CHICAGO March 28 1907

To the Editor—In some cases of scarlet fever I have noticed a sweet chloroform like odor of the breath which seemed the only sign by which in the absence or masked condition of the rash and symptoms a diagnosis could be made. What is the significance of this odor?

DR CHARLES F. STOR

ANSWER—A sweetish odor of the breath is frequently noticed in diabetes, in which it has been attributed to the presence of acetone. A similar odor has been described as occurring in the breath of women during menstruation. A sweetish odor has also been noticed in septicemia and premenia. As acetone is present in the blood in various diseases especially in the infectious like measles scarlet fever etc. It is likely that the sweetish odor of the breath will occasionally be noticed in such cases when not obscured by fever. No definite significance can be attached to such an odor as it may occur under such diverse circumstances. If due to acetone it may not be of great importance. The symptom should suggest examination of the urine however and may be reason for guarding against excessive acidosis which is to a greater or less extent a phenomenon of a large number of infections.

DATE OF DESCRIPTION OF METHODS OF TREATMENT OF CANCER

MERCKE, I. T. March 27 1907

To the Editor—On page 1070 vol XLVIII No 12 is a reference to THE JOURNAL A M A Feb 17 1907 page 541. There was no issue on February 17 nor do I find on page 544 of THE JOURNAL of Feb 16 1904 the reference to Dr John Beard and the pancreatic treatment of cancer. H H

ANSWER—The year is an error. The abstract will be found in THE JOURNAL Feb 17 1906.

The Public Service

Army Changes.

Memorandum of changes of stations and duties of medical officers U S Army week ending March 20 1907

Miller E. W. assistant surgeon left Cuba en route to the United States to avail himself of twenty days leave of absence.

French Charles general staff will proceed at the expiration of Boston Mass for the purpose of directing a lecture on April 17 1907 to the medical officers of the Massachusetts Militia.

Jones Percy I. assistant surgeon now on leave of absence at Fort Irelle Mo will end the expiration of leave at Jamestown Exposition Ground Va and report to the commanding officer Jamestown Incampment for duty as a medical officer medical and sanitary officer.

Smith Floyd L. assistant surgeon ordered to Point N Y to Fort Monroe Va for temporary duty.

Posthill F. L. assistant surgeon reported at San Francisco from Manila I I

Dr. Robert H. H. H.

A. M. & Medical College

1907

Morris Samuel J, asst. surgeon now on duty at Fort Washington Md will furnish such medical attendance at Fort Hunt, Va., as may be needed during the absence of Contract Surgeon Harry Glickrist, Harry L, asst. surgeon, granted leave of absence for one month
Conzelmann F F, contract surgeon ordered from New York N Y to Fort Ethan Allen Vt. for duty
Roberts Ernest D contract surgeon, left Fort Riley, Kans., on leave of absence for ten days
Gunckel G I, dental surgeon arrived at San Francisco, from Philippine service, ordered to Fort McPherson, Ga. and granted leave of absence for two months
Mason G M dental surgeon relieved from duty at Fort McPherson Ga, and ordered to Manila P I for Philippine service
Miller A L contract surgeon arrived at San Francisco on leave of absence for two months eighteen days, from the Philippines Division
Long S M contract surgeon, arrived at San Francisco, on leave of absence for one month from the Philippines Division
Lambkin F B contract surgeon arrived at San Francisco, from Philippine service, and ordered to his home, Baltimore, for annulment of contract
Brars C H contract surgeon left Fort Ethan Allen, Vt for his home Houston, Texas for annulment of contract granted leave of absence for one month
Van Kirk H H contract surgeon returned to Fort Logan Colo from temporary duty at Fort Wingate N M
Love Joseph W contract surgeon granted leave of absence for fourteen days
Bown, Polk D, contract surgeon, granted leave of absence for ten days
Ingalls Raymond E dental surgeon, ordered from Los Angeles Cal to Fort Leavenworth Kans, for duty

Navy Changes

Changes in the Medical Corps U S N, for the week ending March 30 1907

Farwell, W G asst surgeon detached from the *Worden* April 15 and ordered to the *Lancaster*
Schwerin L H, acting asst. surgeon, detached from the Naval Hospital, Norfolk Va and ordered to the *Worden*
Hammar A pharmacist ordered to the Naval Hospital, New Fort Lyon Colo for such duty as he may be assigned.
Holloway J H P A surgeon detached from duty with Naval Recruiting Party No 4 and ordered to the *Indiana*
Ryder C E P A surgeon detached from duty at the Naval Recruiting Station Omaha, and ordered to the *Vermont*
Butler C St J P A surgeon, detached from duty at the Naval Hospital San Juan Porto Rico and ordered to attend course of instructions at the Naval Medical School Washington D C
Brown E M P A surgeon detached from duty under the department of government and sanitation Canal Zone, Isthmus of Panama and ordered to the Bureau of Medicine and Surgery, Navy Department for special duty
Bogan F M P A surgeon detached from duty at the Naval Recruiting Station Baltimore and ordered to attend course of instruction at the Naval Medical School Washington D C
May H A asst surgeon detached from the *Indiana* and ordered to await orders
Inknap J L asst surgeon detached from duty with Marines uba and ordered to the *Kentucky*
Challer W F asst surgeon detached from the Naval Medical School Washington D C April 8 and ordered to *Brooklyn*
Brown H L asst surgeon detached from duty with Naval Recruiting Party No 3 and ordered to attend course of instruction at Naval Medical School Washington D C
Shook F M asst surgeon detached from duty at the Naval Hospital Mare Island Cal and ordered to duty under the department of government and sanitation Canal Zone Isthmus of Panama
Munson F M asst surgeon detached from Naval Proving Ground Indian Head Md and ordered to attend course of instruction Naval Medical School Washington D C
Chappleear F D acting asst surgeon detached from Naval Medical School Washington D C and ordered to duty at the Naval Hospital Pensacola Fla
Castro D H acting asst surgeon detached from Naval Medical School Washington D C and ordered to duty at the Naval Recruiting Station Baltimore.
Curtis, F E acting asst surgeon detached from the Naval Medical School Washington D C and ordered to duty at the Naval Hospital Norfolk Va
Jones A M K acting asst surgeon detached from the Naval Medical School Washington D C and ordered to duty with Naval Recruiting Party No 4

Public Health and Marine-Hospital Service

List of changes of station and duties of commissioned and non-commissioned officers of the Public Health and Marine-Hospital Service for the seven days ended March 27 1907

Pettus W J asst surgeon general, granted leave of absence for four days from March 27 1907
Stoner G W surgeon granted leave of absence for four days from March 18 1907 under Paragraph 180 of the Regulations
Banks C E surgeon leave of absence granted for fourteen days from Feb 21 1907 revoked
Carrington P M surgeon granted leave of absence for three days from March 23 1907 under Paragraph 189 of the Regulations
Lumsden L L P A surgeon granted leave of absence for one month from March 18 1907 on account of sickness with permission to leave his station
Fox C P A surgeon granted leave of absence for one month from March 28 1907
Collins G L asst surgeon granted leave of absence for one day
Lonz H D, asst surgeon relieved from temporary duty at the Government Hospital for the Insane Washington D C and directed to rejoin his station at Ellis Island New York

Guthrie M C asst surgeon relieved from temporary duty at the Government Hospital for the Insane Washington, D C, and directed to proceed to Ellis Island, New York
Porter J J sanitary inspector, directed to proceed to Pensacola, Fla, for special temporary duty
Jackson, J M Jr acting asst surgeon granted leave of absence for 11 days from March 14 1907
Stanton J G, acting asst surgeon, granted leave of absence for three days from March 20 1907
Safford M V acting asst. surgeon directed to proceed to Ellis Island New York for special temporary duty, upon completion of which rejoin his station at Boston
Small D M, acting asst. surgeon, granted leave of absence for 8 days beginning April 15 1907
Tharston E J pharmacist, relieved from duty at Gulf Quarantine Station and directed to proceed to Mobile Quarantine Station, reporting to the medical officer in command for duty
La Grange, J V pharmacist, relieved from duty at Boston and directed to proceed to Savannah Ga reporting to the medical officer in command for duty and assignment to quarters

BOARD CONVENED

A board of medical officers was to meet at Seattle, Wash, March 28 1907 for the purpose of making physical examination of an alien Detail for the board Asst. Surgeon H G Ebert, chairman Acting Asst. Surgeon F R Underwood recorder

Health Reports

The following cases of smallpox, yellow fever, cholera and plague have been reported to the Surgeon General Public Health and Marine Hospital Service, during the week ended March 20 1907

STEPHEN A HEMMI M.D. to Miss Helen Librenz, both of Chicago, at Springfield, March 23

BRUNO L SCHUSTER M.D. to Miss Louise Kumz, both of Milwaukee, Wis., in Chicago, March 21

HARRY J MOSS M.D., Philadelphia to Miss Adeline E Grobman of Woodbine, N J, March 17

KENNETH NOBLE, M.D. to Mrs Bertha Z Schuenicht both of Milan, Mich., at Monroe, Mich., February 28

LUCIUS F C GARYN, M.D., formerly governor of Rhode Island, to Miss Sarah Emma Tomlinson, both of Lonsdale, R I, April 2

Deaths

Reed Brockway Bontecou, M.D. Vermont Academy of Medicine, Castleton 1847, a member of the American Medical Association and delegate to the International Medical Congresses of 1887 and 1890, surgeon of the old Twenty fourth Regiment New York State Militia, since 1849, surgeon throughout the Civil War, serving first with the Second New York Volunteer Infantry and later as brigade surgeon of volunteers, on duty in the surgeon general's office Washington 1862, and afterward chief military officer of all hospitals at Beaufort N C in charge of the Haverford U S Army General Hospital, Washington from 1863 until its discontinuance in 1866 one of the most extensive contributors to the Medical and Surgical History of the War of the Rebellion, brevetted lieutenant colonel and colonel of volunteers in 1865 for faithful and meritorious service during the war, first surgeon of the Troy (N Y) Hospital, surgeon at the Marshall Sanitarium, Troy, since 1880 attending surgeon at the Watervliet Arsenal since 1870 who contributed much to medical literature and especially to military surgery said to be the originator and first to practice the application of photography to the history of military surgery as well as the first in this country and the second in the world to attempt to repair a typhoid perforation (in 1887) died at his home in Troy, N Y March 27 after an illness of one week aged 82

George G Wheelock, M.D. College of Physicians and Surgeons in the City of New York 1864, for a year in charge of the Army General Hospital Savannah and later house surgeon at the New York Hospital formerly assistant demonstrator of anatomy lecturer on physical diagnosis trustee registrar of the board of trustees and treasurer of the alumni association of his alma mater later a trustee of Columbia University, manager of the Vanderbilt Clinic and president of the Sloan Maternity Hospital a trustee of the New York Dispensary, New York Institution for the Blind, Children's Aid

Society, and president of the State Charity and Aid Association, died at his home in New York City, March 22, from heart disease, after an illness of two years, aged 68

Jerome B Thomas, M.D. Jefferson Medical College Philadelphia, 1858, assistant surgeon of the Twenty fourth Illinois Volunteer Infantry, later surgeon in chief of the government hospitals at Bowling Green, Ky., and Gallatin, Tenn., after ward acting medical director on the staff of General Pain and, at the close of the Civil War, in charge of the Army General Hospital, Nashville, who practiced in Wyandotte, Kan., after the war, and since 1888 had been governor of the Central Branch of the National Soldiers' Home for Disabled Volunteer Soldiers, National Home, Dayton, Ohio, died at his residence, March 5, after an illness of four weeks, from heart disease, aged 71

William Carr Glasgow, M.D. St Louis Medical College, 1869, a member of the state and county medical societies, professor of clinical medicine and laryngology in Washington University Medical Department president of the American Laryngological Society in 1890, fellow of the American Climatological Society, consulting physician on diseases of the throat and chest at the St. Louis City Hospital and the Martha Parsons Hospital for Children, died at his home in St. Louis, March 22, from uremia, after an illness of two years, aged 62

Henry Root, M.D. New York University Medical College, 1859, of Whitehall, N Y, a member of the state and county medical societies and for 12 years secretary of the latter, a veteran of the Civil War, in which he served as surgeon of the Fifty fourth and Fifty eighth New York Volunteer Infantry and was brevetted lieutenant colonel, for several terms vice president of the Society of the Army of the Potomac, health officer of Whitehall for many years, died suddenly at Saratoga, March 20, from cerebral hemorrhage, aged 70

William D McCarthy, M.D. Cooper Medical College, San Francisco, 1882, a member of the state and county medical societies, major and surgeon of the First California Infantry, U S V, during the Spanish American War, who served with that regiment in the Philippine Islands died at his home in San Francisco, March 15, from rheumatism, contracted in the service, after a long illness, aged 46

Hiram M Keyser, M.D. Rush Medical College Chicago, 1863, on duty at Camp Douglas, Chicago, in 1862 and 1863, receiving and disbursing agent for the territory of Montana in 1866 and 1867, representative to the Thirty fifth General Assembly of Illinois, for several terms mayor of Moline, Ill., died at his home in that city, January 24, from angina pectoris, aged 72

George Henry Van Wagner, M.D. Albany (N Y) Medical College, 1881 a member of the state and county medical societies, at one time president of the county medical society, for many years health officer for the town of Poughkeepsie, and the village of Wappingers Falls, N Y, died at his home in Wappingers Falls, March 19, after a lingering illness, aged 55

Otto Albert Weigand, M.D. College of Physicians and Surgeons in the City of New York, 1890, a member of the American Medical Association one of the best known young practitioners of Hudson County, N J died at his home in Hudson City N J March 23 from tuberculosis, after an illness of more than three months, aged 38

Amos J Jones, M.D. College of Physicians and Surgeons Baltimore, 1868, a member of the state and county medical societies for four years a soldier in the Confederate service during the Civil War, and for the last four years health officer of Duplin County N C, died at his home in Kenansville, March 18 after a brief illness, aged 63

Thomas B Lacey, M.D. Northwestern University Medical School, Chicago 1875 professor of surgery in the John A. Creighton Medical College Omaha, and for more than 30 years a practitioner of Council Bluffs Iowa died at his home in that city March 25, from syringomyelia, after an illness of six years, aged 55

George Miller Hull, M.D. Medical Department Omaha University, 1885, a member of the American Medical Association and secretary for many years of the Buffalo County Medical Association died at his home in Kearney, Neb. February 27 after an illness of nearly a year, aged 43

James William Murfin, M.D. St Louis College of Physicians and Surgeons, 1861, a member of the American Medical Association died at his home in Vernon Ill., February 23, after an operation for the removal of the gall stones, after an illness of four days aged 51

Pemberton Dudley, M.D. Homeopathic Medical College of Pennsylvania, Philadelphia, 1861, formerly dean of Hahnemann Medical College, died at his home in Philadelphia, March 25, as the result of injuries received in a street car accident in December last, aged 69

William B. Insh, M.D. Western Pennsylvania Medical College, Pittsburgh, 1894, a member of the American Medical Association, and for 10 years a practitioner of Pittsburg, died at his home in that city March 22, from pneumonia, after an illness of six days, aged 36

Charles E. McAdams, M.D. Missouri Medical College, St. Louis, 1869, a member of the state and county medical societies, of Wichita, Kan., for several years a councilman of that city, died suddenly in Kansas City, Mo., March 19, from heart disease, aged 61

Hezekiah D. Fuller, M.D. Albany (N. Y.) Medical College, 1879, a member of the state and county medical societies and of the Fox River Valley Medical Association, died at his home in Berlin, Wis., March 20, from uremia, after an illness of two days, aged 57

Harland S. Boardman, M.D. Homeopathic Hospital College, Cleveland, 1877, formerly president of the Vermont State Homeopathic Society, died at his home in Montpelier, March 21, from organic heart disease, after an illness of several years, aged 56

Owen Eugene McCarty, M.D. Trinity Medical College, Toronto, 1890, a member of the American Medical Association, and a practitioner of Niagara Falls, N. Y., since 1892, died at his home, March 25, after an illness of several months, aged 36

George Elmer Sanford, M.D. University of Michigan, Department of Medicine and Surgery, Ann Arbor 1875, a member of the state and county medical societies, died suddenly at his home in Saline, Mich., March 18, from heart disease, aged 56

Albert Fox, M.D. Eclectic Medical College of the City of New York, 1871, once president of the Eclectic State Medical Association of New York, died at his home in Waterbury, Conn., March 20, from senile debility, aged 81

George W. Hunt, M.D. Castleton (Vt.) Medical College, 1854, dean of the medical profession of Sullivan County, N. H., died at his home in Cornish Flat, N. H., March 3, from nephritis, after an illness of ten days, aged 77

Mary E. Van Schoonhoven, M.D. University of Michigan, Department of Medicine and Surgery, Ann Arbor, 1891, died at her home in Salt Lake City, Utah, March 20, from valvular heart disease, aged 64

Edward L. Carpenter, M.D. University of Louisville Medical Department, 1886, a school trustee of Louisville for two terms, died at his home in that city, March 23, after an illness of several weeks, aged 41

Joseph Marshall, M.D. St. Louis Medical College, 1853, a veteran of the Civil War and for many years a practitioner of Normal, Ill., died at his home March 21, from dropsy, after a long illness, aged 74

Edward J. Jenner, M.D. Eclectic Medical Institute Cincinnati, 1878, formerly of Birds, Ill., died suddenly at his country home near Lawrenceville, Ill., from heart disease, March 22

Thomas W. Davis, M.D. Western Reserve University Medical College, Cleveland, 1857, for half a century a practitioner of De Witt County, Ill., died at his home in Wapella, March 16, aged 79

John J. Hopkins, M.D. New York University Medical College, 1874, a surgeon in the Confederate service during the Civil War, died at his home in Upper Tract, W. Va., March 24, aged 65

Charles R. Brown, M.D. New York Homeopathic Medical College and Hospital, New York City, 1873, died suddenly at his stable in Lynn, Mass., March 21, from heart disease, aged 70

William L. Linder, M.D. Medical College of the State of South Carolina, Charleston 1900, was shot and instantly killed in his office, in Union S. C., March 25, aged 29

William Steward, M.D. Bellevue Hospital Medical College, New York City, 1886, died in the Brooklyn Hospital from pneumonia, Dec. 24, 1906, after an illness of one week

Charles F. Morcom, M.D. New York University Medical College, 1889, died at his home in New York City, March 23, from cirrhosis of the liver

Morris E. Michel, M.D. Medico-Chirurgical College of Philadelphia 1893, died at his home in Pittsburg, Pa., March 20, aged 62

BOSTON MEDICAL LIBRARY MEETING

Held Feb. 13, 1907

DR. RICHARD C. CADOT, Chairman

MEDICAL SUPERVISION OF SCHOOL CHILDREN

Physical Training in the Boston Public Schools

DR. JAMES B. FITZGERALD said that gymnastics was introduced in the Boston schools in 1890 along the lines of Swedish gymnastics. A director was elected in 1891, but this form of training has never been fully established in all the Boston schools. It was proposed by the superintendent of schools in 1880, but failed to be approved by the school committee. Enebuske's book was used, and, under the regular classroom teachers, exercises tried in school rooms, halls, etc. In 1899 Dr. Fitzgerald became the director. He found that some teachers are better in this line than others and wherever possible has this "departmental" arrangement. Instead of the book there are a set of graded cards devised by Hartvig Nis son, physical director of the schools in Brookline. All exercises are at the word of command. None are rhythmic or automatic. There is no music. There is a definite order for each day, including facing, heaving, stretching, balance, back, abdomen, jump and breathing in regular sequence. Primary grades devote twelve minutes per day, and these exercises are more in the form of play. Grammar grades exercise sixteen minutes each day and seek West Point ideals. For purposes of play some simple gymnastic apparatus has been installed in ten of the school buildings. There should be a special teacher of physical training for every grammar school district.

The best work in physical training in the schools is done by the girls in the high schools. They are required to spend two periods of forty-five minutes each week in gymnastic work, and excellence counts several points in their records as scholars. They need, however, to have medical examination.

The high school boys do little because of the military drill. It would be well if the schools were well rid of this. Some thing has been done in the supervision of competing athletes, however, and now all such competitors have a physical examination which certifies to their fitness. There are two instructors in athletics. In all the school athletes examined by the reader, he had found only one case of athlete's heart, no pulmonary tuberculosis and rarely any cardiac lesion. Their legs are, however, usually much better developed than their

chests. The department now has one director, four assistants and fifteen teachers. It needs athletic fields and more teachers for boys.

School Hygiene As It Is and As It Ought to Be.

DR. SAMUEL H. DURGIN said that during the more than 30 years that he has been a member of the Boston Board of Health there has been much progress in the hygiene of school buildings. Thus privy vaults and cess pools are abolished. There are separate toilet bowls and wash bowls. Basements are well lighted. Fresh air is obtained for the school rooms by air shafts and the needed power. Pupils are properly seated and not overcrowded. Still much is needed in the way of new buildings, school play grounds, etc. These matters are now in the hands of the school house commission, a very able body of men.

In 1894 agents of the Board of Health, physicians, were appointed to daily inspect the schools. Cases are referred to them by the teachers, diagnoses made, and the pupils either returned to the school room or sent home. Advice is given as to the best care for the others who may have been exposed to a contagious disease. Vaccinations are inspected and pediculosis detected. Each medical inspector receives a daily bulletin of all cases of contagious disease reported in Boston during the previous day and is expected to attend to the isolation of such cases in their homes. By examination of rashes and desquamations and cultures of throats and noses they determine when children shall be allowed to return to school. Other cities have followed Boston in this medical school inspection, and now the State of Massachusetts has made it obligatory in all cities and towns. There are many ways in which this inspection can be improved. It should be aided by trained nurses. All abnormalities should be detected, not only of sight and hearing. Necessary treatment should be insisted on. All exposed children should be followed up and examined. The school nurse, already a success in New York City, is now assured for Boston.

Physical Welfare of Public School Children.

DR. S. C. BADGER's paper was a preliminary report of a committee of five physicians appointed by the Boston School committee to study the lowest three grades. They advise that artificial light be introduced into these school rooms and, when necessary because of dim light, schools should be dismissed. For the same reason windows should be washed more often. Two sessions are better than one. Recess in the afternoon should be longer and include more play. In the late afternoon there should be games and manual training. Grade I should be limited to 25 pupils, Grade II to 35, and Grade III to 45. Backward pupils should be studied by themselves. School nurses are needed. School yards should be open to the children after school hours and should have swings and such like apparatus, and when possible school gardens. Pupils should be allowed to continue play on the school grounds and public playgrounds after the close of the afternoon session.

As to medical inspection, the real inspection is done by the teachers and they vary in their skill and interest in this subject. It is desirable that the physician should observe all the children and not merely those referred to him by the teachers. This inspection has not been of much importance.

The work done seems to show that the public schools are not such great centers of infection as they have been thought to be.

The school nurse will help greatly as will co-operation by teachers. The value of special examinations are indicated that in one building with 1,275 pupils where the eyesight was tested this last year, 10 per cent have been fitted to glasses. The committee found the children generally well nourished and healthy, with but few cases of apparent neglect.

Medical Supervision versus Medical Inspection.

DR. THOMAS B. HARRINGTON maintained that the latter was not adequate. Physician, teacher and parent must co-operate, and often do not, in order to fit the child and the curriculum. Several foreign countries already have medical supervision of the schools, notably Austria and Japan. This medical supervision must have due authority, and in many matters besides infectious diseases. In this latter matter it would be better for the teacher to exclude suspicious cases and report to the

board of health. Their inspectors and nurses should then follow up the cases in their homes. Something of this sort has already been done in New York City, and as a result, while in 1902 there were detected in the public schools 10,562 cases of contagious diseases, in 1903, with the new plan, only 1,001 were so sent home, others being detected in their homes or prevented by proper attention to the first case in the home.

Medical supervision, on the other hand, is a much wider subject and includes a study of the physical and mental development of the child. Not all grow equally. All develop best in certain periods. Thus the medical man must study and should control. The school should be a continuation of the home and the home should be the strength of the school.

DISCUSSION

GEORGE H. MARTIN, secretary of the State Board of Education, told of the effort being made to interpret practically the words of the new law which require that "each child shall be examined annually for any defect or disability which may interfere with school work." Governor Guild asked a committee consisting of three members of the State Board of Health, three members of the State Board of Education, and three prominent physicians to consider the matter and report a plan. They appointed a subcommittee consisting of Dr. Robert W. Lovett, Dr. Charles Harrington, and Mr. Martin to prepare a circular to be sent to the medical inspectors throughout the state to secure uniform intelligent inspection. Conferences were held with specialists of all kinds and they were asked what defects they would expect to meet among school children, and the indications. As it was found that practically, in most places in the state this inspection must be made by the teachers, these specialists were asked to each prepare a brief, simple statement. This material was then gathered and arranged by the committee, and is now being printed. This circular, signed by those experts who are authority for its statements, will go to every teacher and medical inspector in the state, and is likely to form a most efficient aid.

DR. ARTHUR C. JELLY told of his work among the backward scholars. Graded classes are for the average pupil. For many years there have been "ungraded" classes for the backward pupils, and now there are seventy such classes in Boston. The same methods are employed as in the graded classes, the object being to coach them in some special lines, e. g., foreign born, frequently ill, slow developing, irregularly developing, deaf, partially blind, poorly nourished, or mentally deficient children.

In 1898 three classes were started especially for these, and in 1902, when Dr. Jelly took charge, four more such classes were established. There are 16 children in each, or 105 in all. At first they were chosen by the teachers, and lowest types were so separated. These were not capable of doing anything and the service was thrown away. Now the effort is made to induce parents to send such children to the School for Feeble Minded at Waverly. This gives a chance for the admission to these special classes of less extreme types, and often these can be so helped by the special training that they are able to return to the regular graded classes. It is thus possible to instruct the teachers and less obvious defects are now noticed by them and remedied. More such special classes are needed.

DR. JOEL E. GOLDTHWAITE said that the school system in Boston is broadly a great success. The problems are varied. With 40,000 pupils in the lowest three grades the only surprise is that the curriculum so well meets their varied conditions. Physicians must be careful not to condemn the system because of a few isolated examples of faults which come to their individual notice. Doubtless a much better system can be developed, but meanwhile be temperate and helpful in criticisms. The school committee and the teachers are remarkably efficient, and all suggestions of the committee were well received.

DR. WILLIAM H. POTTER said caries of the teeth is one of the most common defects among children. It disables insidiously, affecting mastication, digestion, nutrition, weight. Of 700 pupils examined in one building in Brooklyn this past year, 50 per cent. had poor teeth, 25 per cent. fair teeth and 25 per cent. good teeth, by this being meant teeth which had no readily observable defects."

DR CHARLES PUTNAM said that the nearly 500 boys who are sent by the courts to the parental school at Roxbury, or to the Rainsford Island in Boston Harbor and put under the care of the trustees for children, all of them, nearly 500, have the benefit of regular examinations of teeth, sight and hearing. Surely it is proper that children who are not bad should have the same privileges.

MR. JOSEPH LEE, of the Civic League, told of two bills now before the legislature, one to combine the public baths, gymnasiums and playgrounds under one paid commissioner to be appointed by the mayor, with the advice and consent of the aldermen. This he opposed as not being practicable or likely to benefit the children. The other is to put the playgrounds and outdoor gymnasiums, as well as the public school yards, under the control of the school committee. This is based on the idea that they can and should care for the physical as well as the mental well being of the children. Boston has playgrounds valued at \$4,000,000, and appropriates \$50,000 annually for their maintenance. Results are now being obtained. Supervision is needed. Men and big boys monopolize the spaces for baseball, etc. Children dare not go there. There are not many professional playground directors. The school committee is already in the business. The best teachers outdoors are those who teach indoors. One of the best places to determine a child's mental ability is while at his play. Such a man of the right character can get out all the scholars and not merely those who are proficient.

Attention was called to the International Congress of School Hygiene to be held in London, England, Aug 4-9, 1907.

NEW YORK ACADEMY OF MEDICINE

Regular Meeting, held March 27, 1907

The President, DR JOHN A WYETH, in the Chair

SYMPOSIUM ON TYPHOID FEVER.

The Typhoid Epidemic in Berwick, Pa.

DR J H BOWMAN, Berwick, said that for two winters in succession Berwick has been visited by an epidemic of typhoid fever. In the winter of 1906-7 the epidemic began in October, and new cases were reported until Jan 1, 1907. The total number of cases to March 1 was 114, with 9 fatalities. Berwick and its vicinity has a population of 15,000 and is dependent for its water supply on the Susquehanna River and several mountain streams. It is situated 41 miles below Scranton. The sewage of Scranton, as well as that of Wilkes barre and Pittston, empties into the Susquehanna River. Soon after the outbreak of typhoid the water was turned off from the river and was not turned on again until February 15. An examination of the water from all sources has been made, but the presence of typhoid bacillus can not be demonstrated. An inspection of the water sheds has also failed to reveal the source of the infection. The dairies have likewise failed to show the cause of the outbreak. Dr Bowman concludes that the water was responsible for the epidemic and that the river probably caused the first cases and that these cases infected the mountain streams.

The Typhoid Epidemic in Pittsburg

DR J T EDWARDS Pittsburg said that typhoid fever has been present continuously in Pittsburg since 1873, or during the entire period of available statistics. Certain years or groups of years show higher percentages than others, but the mortality has always been high as compared with other American cities. The average mortality from 1880 to 1906 was 107 per 100,000 population. The lowest rate was 55 per 100,000 in 1894 and the highest 158 per 100,000 in 1882. It is evident that a predominant etiologic factor is at work continuously, but with varying intensity. The present high rate period began in 1899. The predominant cause was an infected water supply, although other agencies and conditions were also at work. The general water supply of the city is drawn from two intakes in the Monongahela River and two in the Allegheny River, the water is pumped directly into reservoirs and distributed to the people. Several wards in the city are supplied by corporations one having its intake about a mile farther up the river than that of the city supply. There is said to be some filtration here by means of a crib in the river

bed. One ward is supplied by a corporation which has its intake farther up the Monongahela River than the others and has installed an infiltration plant. This ward is at present practically free from typhoid fever. Both rivers have a large population in towns on the water's edge. There are larger towns along the Monongahela than along the Allegheny, and one would expect more typhoid in the portions of the city supplied by that river, but this is not the case. The Monongahela has a slow current and in low water stages is said to be pumped out and put back five or six times during its course. One of these times it must run back through the sewers of a town.

The mines and mills along the river introduce acid enough into the water to render it acid during low water. Five parts of sulphuric acid to 100,000 parts of water is fatal to typhoid germs in one and one-half hours. The river reaches a much higher percentage than this. The objection to this theory is that the river is alkaline during a greater part of the year and typhoid fever was prevalent in August when the water was low. The heating of large quantities of water by manufacturing plants along the course of the river also acts as a corrigent. Four large establishments pump 178,000,000 gallons per day and heat five and three-quarter millions gallons. Many others also use large amounts and return it in a sterile condition. During the winter 1905-6 typhoid prevailed in a number of boroughs above Pittsburg on the Allegheny and the March thaw probably accounts for the large increase in the number of cases reported during the month of April. No considerable number of cases could be traced to the milk supply. Since July, 1905, there has been a progressive increase in the number of cases, and during the year 1906 there were 5,720 cases with 508 deaths.

In general, it may be stated that typhoid fever was more prevalent in those districts where the standard of living is lowest. This class of people are less likely to boil the water and there are greater opportunities for contact infection. A large percentage of cases occurred among immigrants from Austria Hungary, Russia and Italy. A municipal filtration plant is now near completion, and it is hoped that this will greatly diminish the ravages of this disease, which destroys on an average 300 of the most productive part of the population each year. The action of the state looking toward the prevention of pollution of streams throughout the state holds another promise of relief.

The Typhoid Epidemic at Scranton

DR J M WAINWRIGHT, Scranton, said that while reliable morbidity reports are not at hand, and while the disease has been constantly present in that city, it has not prevailed to any great extent as compared with other American cities. The fall rise in Scranton has not been nearly as great as in other cities. The sudden onset of the epidemic points to some sudden and large pollution of the water. A map showing the Scranton water supply, the larger part of which came from the Elmhurst reservoir, shows that the principal tributary of the Elmhurst reservoir was Roaring Brook which ran through Moscow, a village of about 800 inhabitants, and also through a hamlet of about 200 inhabitants. Until last September the water from the Elmhurst reservoir was delivered over a spillway and allowed to run several miles into a storage reservoir. This reservoir was about 2,000 feet in length and the water displaced itself in every two to four days. A rail road runs near the brook and also one on either side of the Elmhurst reservoir. In the latter part of September the water was piped directly from the Elmhurst reservoir to the city cutting out reservoir. The water was taken from near the bottom of the reservoir instead of over the spillway.

During the first week in December, 11 cases of typhoid fever were reported. This time suggested close connection with a heavy snowstorm on November 15, followed by warm rains, so that it was probable that a fecal accumulation was washed suddenly into the water. Considering the epidemic to have extended over December, January and February there were 1,155 cases reported and 111 deaths. The map of the city shows very strikingly that the distribution of the cases corresponds with the Elmhurst water supply. In portions of the

city having another water supply there were only 28 cases, and these were persons who were employed or who visited frequently in that part of the city supplied by the Elmhurst reservoir. After a painstaking search of the entire water shed by both city and state authorities, the origin of the infection could not be located, this was probably due to the multiplicity of possibilities.

Dr Wainwright drew the following conclusions from this epidemic: 1 All cases of typhoid fever ought to be reported promptly, as when this is neglected grave danger signs often pass unnoticed. 2 Municipal ownership was an advantage, as it eliminated the harm that a private corporation can do during an epidemic in its effort to guard the capital stock at the expense of disaster to the people. 3 The numerous nuisances that have been sustained along this water shed demonstrated the necessity of rigid police inspection of the entire water shed by inspectors employed by and for the people and not by the water company. 4 Frequent bacteriologic and chemical examinations of the water are another safeguard. 5 In times of epidemic the water supply should be changed, if possible. The necessity of boiling water and milk should be hammered into the people, and all possible precautions should be taken to protect the milk supply. The spread from individual cases should be prevented by visiting nurses, circulars of instruction and the free distribution of some one effective antiseptic. Too many antiseptics confuse people. 6 Typhoid fever is to a very great degree a directly communicable disease. 7 Physicians and sanitarians must recover from their habit of speaking of a certain number of cases of typhoid fever as normal, because typhoid is caused by imbibing more or less directly the feces of a sick man. The only normal for a civilized community is no case at all.

Bacteriology of the Blood in Typhoid Fever

DR WARREN COLEMAN said that up to 1904, 75 per cent. of typhoid patients whose blood was examined revealed the presence of the typhoid bacillus. Broths were used in the earlier experiments, but the method now used is to take 90 c.c. of ox bile, 10 c.c. glycerin and 2 grams of peptone. The mixture is distributed in small flasks, containing 20 c.c. each and is sterilized. Three of these flasks are used for every examination and about 3 c.c. of blood is run into each. The flasks are then incubated until the following morning, when streaks are made from each over the surface of a litmus lactose-agar plate. If the micro organisms are present they may be observed in five or six hours. If the growth does not red den the medium and the bacillus is found to be one resembling typhoid, the Widal reaction with immune serum is applied. In this way one can determine within twenty four hours whether a case is one of typhoid.

Since using the ox bile method a much larger percentage of positive results has been obtained, in fact, the results now obtained show that the bacillus is present in the blood in practically all cases of typhoid fever. Out of 224 examinations in the first week of the disease, 200, or 89 per cent., were positive. Of 484 examinations made in the second week of the disease, 353, or 73 per cent., were positive, of 268 examinations made in the third week, 178, or 66 per cent. were positive, of 103 examinations made in the fourth week, exclusive of relapses, 15 or 26 per cent. were positive. Therefore, the percentage of positive results is greatest in the first week of the disease and thereafter steadily declines. This does not indicate that the bacillus has disappeared from the blood in negative cases, but points to a diminishing number of bacilli, whose presence imperfect methods fail to reveal.

From investigations in regard to the absorption of the bacilli from the peritoneum and from the fact that the lymph nodes and spleen contain such enormous numbers of bacilli, it may be concluded that in typhoid fever the bacillus first finds its way from the alimentary tract to the lymphopoietic system, including the spleen, where it is developed chiefly and from whence it finds its way into the blood stream. It seems doubtful whether the bacillus multiplies in the blood, its presence means simply an overflow from the lymph organs. The presence of typhoid bacilli in the blood consequently does not constitute a true septicemia. The destruction of the bacilli proceeds most rapidly in the blood, and hence the disease

is caused by the destruction of vast numbers of bacilli in the blood with the liberation of their endotoxins. It is accordingly irrational to believe that the course of the disease can be affected by intestinal antiseptics, because after the invasion of the body proper by the bacillus the battle ground shifts from the intestine to the blood.

There appears to be a definite relation in the evolution of typhoid fever between the symptoms and the bacillemia. The intensity of symptoms in the early stages of the disease corresponds to the active growth of the bacilli. They invade the blood stream in increasing numbers and are there destroyed. Then comes the stationary period when the ratio of growth and destruction appear to be uniform. The steep curve period corresponds to the diminishing bacillemia and defervescence to complete disappearance of the bacilli from the blood. Degenerative changes occur only in the presence of active growth and destruction of the bacilli. Relapses are probably caused by the persistence of some bacilli in the body and not by reinfection. The bacillemia apparently bears no relation to the type or severity of the disease, except as regards the number of bacilli. The bacilli are found in the blood with the same persistence in the mild as in the severe cases, and in the cases of short as well as in those of long duration. The definite establishment of the nature of these short duration cases would be of immense value from the epidemiologic standpoint.

A bacteriologic examination of the blood in 33 cases of relapse resulted in the recovery of the bacillus in 90 per cent. of the cases.

DISCUSSION

DR. MORRIS MANGES, in speaking of the direct infection of one subject by another, told of the case of a woman baker in Germany. All those who ate her bread developed typhoid fever. The typhoid bacillus was found in her feces, and inasmuch as she used the same toilet and prepared the food for the others who contracted the disease, the source of infection was not hard to find. He cited another case of a woman who had some intestinal trouble and fed only on a beef diet. Her cook had a slight diarrhea, but the feces contained a number of spirilla, thus showing the source of infection. It is difficult to find the foci of infection after the epidemic has passed away. The fact that the acidity of the river water in Pittsburgh failed to do away with the typhoid germs shows how fallacious is the antiseptic action of the gastric juice on typhoid bacilli. He called special attention to the fallaciousness of statistics in small towns.

DR SEDGEWICK said that the summary of infection is Food, fingers and flies.

TEXAS State Board of Medical Examiners, Austin April 30 May 2 Secretary Dr T T Jackson San Antonio

TEXAS Eclectic Medical Board Dallas about April 25 Secretary, Dr L S Downs Galveston

Rules for Conducting Examinations in California—The following set of rules governing examinations for license to practice medicine in California were compiled by Dr J C King, ex president of the Board of Medical Examiners of that state:

1 Regular meetings of the Board of Medical Examiners of the State of California will be held on the first Tuesday of each April, August and December. Examinations will be held on the third Tuesday of each June, September and December, unless otherwise ordered by the board. Only necessary routine business may be transacted at any meeting held on a first Tuesday of any month.

2 The deliberations of this board shall be governed by Robert's Rules of Order, so far as they do not conflict with the state law under which this board is organized, nor with other rules adopted by this board.

3 Any motion to add to, rescind, alter or suspend these rules or any part thereof, shall be submitted to the committee on rules without debate. On the favorable report of the committee, said motion shall be put before the board for action, but, if adopted, shall not become operative until the next regular meeting.

4 There shall be three standing committees, to wit: One of three members, on rules, one, of three members, on credentials of applicants, one, of two members, on auditing of accounts.

5 In determining the standard grammar and high schools, academies, colleges (other than medical) and universities, the opinion of the recorder or of the credential committee of the University of California shall be taken as a guide by this board.

6 As applications are received, the secretary shall immediately place at the disposal of the committee on credentials all documents relating to each and every new applicant. This committee shall, on the first day of each regular meeting, report to the secretary the result of their investigation. The secretary shall thereon, within twenty-four hours, mail to the address of each applicant a permit to take the examination, or, in lieu of such a permit, a statement showing in what respect the credentials and documents of the applicant are incomplete or defective, together with notice that said applicant may appeal, in person or by attorney, to the full board at its next meeting, specifying date and hour.

7 An adjourned meeting of the board shall be held in San Francisco at 9 a. m., on the day on which each examination shall begin. Prior to this meeting the committee on credentials shall present to the board, and to each individual member thereof, a formal, complete and typewritten report. This report shall include a list of the names of applicants to whom permits to take the examination shall have been issued, it shall specify, as regards each applicant individually, the reason why his or her credentials or documents, or any part thereof, shall have been deemed incomplete or defective by said committee. Thereon, any applicant to whom a permit shall have been refused or not issued, may appear before the board, in person or by counsel, and may present an amendment to his or her credentials or documents, or may appeal to the board on the decision of the committee. In case the amendment is accepted or the appeal sustained by the board, the secretary shall at once issue a permit to said applicant.

8 Immediately before an examination begins, a numbered envelope will be handed to each applicant. In this envelope the applicant shall insert his permit, after having signed his name and written his address on said permit, and shall then seal the envelope. Said envelope shall then be returned to the custody of the secretary and shall not be opened until all the markings connected with that examination shall have been completed and then only in the presence of the board. The number of the envelope shall become the number of the applicant whose name shall have been inserted therein. Each applicant shall remember his or her number and shall inscribe it, in plain figures, on the exterior of each set of examination papers. No other mark shall be placed on any paper whereby the identity of the applicant may be discovered.

9 Each member of the board, to whom a subject for examination shall have been allotted, shall prepare a list of questions, at least ten of which must be answered by each applicant.

10 All questions must be written with ink, in English.

11 Each question shall be graded and marked separately on a scale of 1 to 10, in plain figures in ink, on the margin of the examination paper. The total attained shall then be computed and marked on the exterior of said paper.

12 Each of the following, when made a part of any examination, shall constitute one question: (a) Identification of microscopic preparations, (b) identification of gross pathologic preparations, (c) clinical examination of patients, (d) any other practical work. In all such cases questions must be answered in writing as a part of the examination paper, in order that the identity of the applicant may not be revealed to the examiner.

13 No oral, clinical or other form of examination shall be conducted in a manner that will permit the applicant to reveal the identity of his or her number to an examiner, or to any other person.

14 During an examination no applicant shall consult, or open for inspection, any book, notes or other aids to memory, hold any communication with any other applicant, smoke tobacco, leave the room prior to the completion of his paper, unless accompanied by a member of the board, or by an inspector appointed by the board, create any unnecessary noise or disturbance, introduce into the room any visitor or friend. Violation of this rule will be punished by exclusion from the examination.

15 Two hours shall be allowed for the completion of papers on each subject.

16 On its completion, each examination paper shall be deposited by the writer thereof, in a ballot box to be provided for that purpose by the secretary. No examiner nor other person shall be permitted to handle or to inspect any such paper until after its removal from said box. No paper shall be removed from said box until after all papers relating to the same subject shall have been deposited therein, and then only by a member of the board. Each applicant is absolutely forbidden to reveal the identity of his or her number to any examiner, or to any other person, under penalty, if discovered, of summary rejection.

17 Each examiner shall be responsible for the removal from the ballot of all papers relating to the subject allotted to him, for the correct marking of the same, and for the delivery of the same to the secretary before 10 o'clock a. m., of the day next succeeding the last examination.

18 Section 1 On the day following the last day of examination the secretary shall record on a chart prepared for the purpose the number of each envelope, and beneath that number the markings attained in each subject by the examination papers correspondingly numbered.

Sec. 2 The numbers showing an average work of not less than 75 per cent, and also a mark of not less than 60 per cent on any one subject, shall be deemed to have passed the examination.

Sec. 3 When it appears that any number has attained an average of at least 75 per cent, and yet has failed to attain at least 60 per cent on any one or more subjects, then the board shall review papers so numbered, so far as they relate to defective subjects, and shall, by vote, re-mark each answer thereof, and the result arrived at by the board shall be inserted on the chart, instead of the original marking.

Sec. 4 All numbers which shall finally appear to have attained an average of less than 75 per cent, or which shall have attained less than 60 per cent on any one or more subjects, shall be deemed to have failed.

Sec. 5 The numbered envelopes shall then be opened and the name on the permit contained therein shall be attached to the numbers on the chart corresponding to the numbers on the envelopes, thus determining the identity of each applicant.

Sec. 6 After the numbered envelopes shall have been opened, no change whatever shall be made in the markings or their result, except as hereinafter specified.

19 Within three days after the success or failure of applicants shall have been determined, the secretary shall send, by express or otherwise, to the address of each successful applicant, a license, properly signed and sealed, to practice medicine and surgery in the State of California. And he shall send, by mail, to the address of each unsuccessful applicant a statement showing his or her markings in each subject.

20 Applicants for re-examination must, not later than the first Tuesday of any April, August or December, following the legal interval after their last examination, make application to the secretary for a permit, in the form prescribed for the first examination and accompanied by the same fee, except that no credentials need accompany the application. The secretary shall thereon issue to such applicants permits to take the next ensuing examination.

21 On the last day of each examination the secretary shall return to each applicant at the examination, his or her diploma and other documents, taking therefor a receipt from each specifying all documents delivered.

22 Any clerical error in computing the results of the markings may be corrected at any time by the secretary. But such correction must be reported to the board at its next session.

23 At the meetings in each April, August and December the secretary and treasurer shall present a complete report of receipts and expenditures, which shall be referred to the auditing committee.

Miscellany

An Advertising Quack Wants a Helper

The following advertisement appeared recently in a Chicago evening paper

MALE HELP WANTED

DOCTOR SINGLE REGISTERED IN PENNSYLVANIA, wanted in a Philadelphia advertising office by April 10, must be first-class casetaker, strictly sober, good letter composer typewriter put up prescriptions hours 9-4 6-9 Sundays, 9-2 steady man willing to sign five year contract should send photo highest references or security wages to start, \$840 yearly no board or lodging Doctor 204 2d st. Miami Fla., send full particulars

An answer to it brought forth the literary gem here appended

MIAMI FLA., Feb 28 1907

Dear Sir—Yours to hand and in reply will say that I am a well known specialist in Philadelphia and my laboratory (sic) contains actual fact over 3 to 4 000 different drugs and they are used and not for show I am the only physician who positively cures Syphilis, Bright's Disease, Diabetes Mellitus Kidney and Bladder Disease and Cancers, if I can get at it. Psoriasis Heart Liver Rheumatism Piles all kinds Bronchitis Malaria, Endwated (?) Scrofula Glands Shingles, etc., Spermatorrhea, Impotence and all other curable cases

Whereas I am an old man, hence I must have an honest man who loves medicine and who is not lazy and who tries to follow my method, the Eclectic, Homeopathic, Allopathic, Botanic. My drugs are very expensive by the combination, and hence a physician must be able to make the patient understand that he gets cured that we don't give mercury, calomel saltz etc., but we combine from 12 to 30 drugs and still they do not effect the stomach. I cure Syphilis and I don't care how dangerous cases are but the cost for each mild case \$285 00. Well we have to get from \$350 00 to \$500 00 and in dangerous cases the drugs cost between \$350 00 to \$500 00 and for those cases \$750 00 to \$1 000 00 is not too much. I am no fakir I mean just what I claim, and the most expensive treatment and work has to be done in the first three months, and therefore patients have to pay all or a great deal of amount down and I have proof of all I claim. Now then I need an honest man who will work. All he has to be is a good diagnostician and then study up the cases and then prescribe according to my R.

How are you as a good case taker? That is to take the patients who have the money? To pay my expenses it takes monthly \$2 450 00 now you see that the money has to come in. Now honesty and a good case taker is everything. Then above all a man has to be strictly sober. Then if not sober he can do no business. A man has to start in with \$840 00 the first year without board or \$600 00 and board, but as I said if he is a good man and can increase the income he gets more. If he is not a good case taker, of course I don't want him not even for his board. I am an old man and as I said I need an honest man. Of course you would have to sign a contract for five years with a provision that if you are not capable to fill the bill I can discharge you. Then it must be to you as reasonable as possible. That if you are not a good case taker and not able to follow my method I could not keep you. I am sure a good case taker alone would not amount to much. If the man is not able to cure you know as well as I do that if you could only take the money and not cure the people will say "Oh that's a beat" and my office would soon go to H—

Now please be kind enough to send me your photograph. I generally can have an opinion from the expression of the man's face. Consider this well. Hours 9 to 4 evenings from 6 to 8, Wednesdays and Saturday from 6 to 9 Sundays from 9 to 2.

You have to put up all your own R. you must see to everything. If I am not at home, you to write with machine and dictate a good letter. The composing of these letters is in itself very important. Of course you will also have to sign in the contract that you have never been in my employ and you never have a right to copy my prescriptions or to take addresses or names of patients nor to open an office in Philadelphia or associate yourself with any one else or say I was formerly with so and so using my name nor can you practice outside of my office while in my employ and you must be registered in Pennsylvania without fail.

The position is a good steady one for the right man in the right place. state the age nationality and what college you graduated from. In fact to avoid unnecessary correspondence and time send highest references not from friends and patients but from honorable citizens who know your good as well as your faults.

Yours faithfully

MIAMI FLA. March 5 1907

Dear Doctor—My uncle for whom I write is Registered since 80 in Philadelphia and has practiced since 35 years in Philadelphia. Of course you are responsible as far as Patients goes if you poison any but otherwise no Patient is taken without a Contract that relieves you and my uncle cure or no cure. Now what Uncle wants is a Honest Man strictly sober good talker a Man who will not take a Penny nor Hundreds but who Truly is Honest & of course Uncle Trusts none until he finds him Honest & so long will set Trapp to find it out. If you are the right man you get a good Place if you are A G as I wrote before you're not worth a

Penny to Uncle & if you are the right Man you will get your wages increased but don't Expect it in a Month or 3. You must show your value first & not Expect the Earth or after you find out you are the right Person say here I want the Earth. My uncle is O K all he wants is the Right Man. Send Photo & Ref. He has to decide quickly as my Cousin now takes care of office but my cousin is this kind of a fellow. He knows that he can run the office & wants the Earth hence Uncle has to make a change. Answer and act quick.

One more letter, thanking the nephew for his services as employment agent and suggesting that he send his uncle's name and address so that further correspondence might be carried on direct failed to elicit a reply.

Whether the doctor was able to get the honest man who didn't want "the earth" to take charge of his evidently lucrative practice and at the same time to fulfil the somewhat exacting requirements, all for the munificent sum of \$70 monthly, we know not.

Venesection in Acute Nephritis.—Baccelli treats acute nephritis by withdrawing 200 cc. of blood from a vein in the foot. In a typical case described in the *Poliadnico*, xiv, 18, 1907, the edema of the lids, fever, blood, albumin and casts in the urine indicated severe nephritis a few days after the first stormy onset. The trouble in the kidneys causes lower arterial pressure with increased venous stasis and thrombosis in the finer ramifications of the veins with the glomeruli compressed and paralyzed. Venesection relieves these conditions as if by magic, and Nature then has a chance to heal. In the severer cases he follows the venesection with powders containing sodium sulphate, sodium nitrate and scammony, every five minutes. This stimulates the emunctories very powerfully, but the venesection alone generally aborts the nephritis and prevents its transformation into a chronic phase. In the severe acute case described the venesection was repeated the second day and recovery was soon complete.

DEDICATION OF THE BARLOW MEDICAL LIBRARY OF LOS ANGELES

George H. Kress, M.D.
 LOS ANGELES

The establishment of medical libraries is so desirable a need of the medical profession and at the same time so unusual an event, that every such occasion seems worthy of special mention and record. It is, therefore, with considerable pride that Los Angeles, now a city of 260,000 persons, and the metropolis and natural geographical, financial, social and literary center of that wonderful region known as "The Great Southwest," is able to announce to the world that the medical profession of that section has come into possession of a fire proof medical library building and equipment costing more than thirty thousand dollars and that the institution starts its career of active work with more than five thousand volumes and publications.

For the generous gift of the building and equipment the medical profession is indebted to one of its own members, in fact to one of the younger members of the profession of Los Angeles—Dr. W. Jarvis Barlow, who occupies the chair of clinical medicine in the College of Medicine of the University of Southern California. Dr. Barlow gave the building without any restrictions, but in his honor it has been called the Barlow Medical Library by the board of trustees, who were elected by the members. The books with which the institution starts constituted the former library of the College of Medicine of the University of Southern California. The control of the institution is in the hands of the patron members, these being physicians who subscribe twenty-five dollars annually. As yet there is no endowment and the salary of the librarian and the expense of publications come from dues of patron members, annual members (ten dollars yearly) and of associate members (five dollars yearly).

The building has been erected within eight minutes' distance of the center of Los Angeles, opposite the buildings of the College of Medicine, so that it is accessible both to physicians and to the medical students of the city. The structure itself is virtually a single mass of cement, the architecture being dignified and handsome and the color tones most pleasing. In

addition to the general reading room there are a number of research rooms where physicians carrying on special investigations may leave books and papers without fear of having them disturbed. Light, ventilation and heating arrangements are most excellent.

The influence which this institution will have on the scientific tone and culture of the medical profession of the Southwest is inestimable. That it will be great and that its effects will be far reaching is not to be doubted. In conjunction with the Los Angeles County Medical Association, an organization that now holds weekly city meetings, in addition to maintaining sections in the specialties as well as supporting three branches in

Fig 1—Front view of the Barlow Medical Library

near by towns, the Barlow Medical Library is bound to be a potent factor in the development of scientific progress and in the organization of the medical profession of the Southwest. The Los Angeles profession is grateful because of this new library and proud of the generosity displayed by one of its members in making this institution a reality.

An appeal is herewith made to medical librarians and to members of the profession elsewhere to aid in the work of increasing volumes and publications now on the shelves of the in

Fig 2—Interior view of the Barlow Medical Library

stitution. Medical publications of any kind and reprints of medical articles will be gladly received. Lists of books or reprints may be sent to the librarian of the Barlow Medical Library, 740 Buena Vista street, Los Angeles, who will be glad to give detailed information concerning the needs of the institution.

The first board of trustees elected by the patron members consists of Dr. Milbank Johnson, president; Dr. Stanley P. Black, secretary, and Drs. George L. Cole, William A. Edwards, B. F. Church, John R. Haynes and Fitch C. Mattison. These men,

on behalf of their fellow practitioners of the Southwest, request the cooperation and aid of the profession of other parts of the country in the work of which they are the custodians.

Tumors of Cerebellum and Posterior Cranial Fossæ.—The *Med. Klinik* publishes with its first number in 1907 a supplement containing an article by W. Seiffer presenting the present status of our knowledge on this subject. He explains the contradictory findings of various investigators as due to the more or less gradual development of the tumor. Of all the organs in the body the cerebellum seems to be able to benefit most from compensatory processes. A tumor developing slowly in the cerebellum exhibits entirely different symptoms from one that develops rapidly, without time for the compensating processes to be established. He urges careful record of the consequences of surgical treatment of such a tumor. Every operation of the kind is not only a life-saving measure, but is a most important contribution to the progress of science. The inoperable intracranial tumors seldom cause choked disc or much head ache, but spastic hemiparesis with exaggeration of the reflexes and Babinski's sign are frequent, also alternating hemiplegia, that is, paralysis of one or more of the cranial nerves on one side and of the extremities on the other. There is, further, frequently a total and permanent ophthalmoplegia (which is not total with tumors of the cerebellum), or bilateral spastic paresis of the extremities, sphincter disturbances (seldom observed with cerebellar tumors), eventually also hemitremor and hemianesthesia. Spitzer regards conjugated deviation of the head and eyes toward the sound side as the chief sign of an affection of the pons.

Cost Increases with Purity.—The argument that enforcement of the laws regulating the purity of milk will result in increased cost of the product to the consumer is not a valid one. The price is being advanced anyway. The law of supply and demand will settle that question, as it does all others in domestic and political economy.—*Louisville Monthly Journal of Medicine and Surgery*

Therapeutics

[It is the aim of this department to aid the general practitioner by giving practical prescriptions and methods of treatment for the diseases seen especially in every-day practice. Contributions will be welcomed from our readers.]

Alopecia.

McKee, in the *Lancet Clinic*, states that the first step is to cleanse the scalp and to remove some of the inflammatory exudates. The next step is to apply some antiseptic medication which should not only cover the scalp, but also penetrate into the hair follicles. Through this cleansing process and disinfecting the natural oil of the scalp will be removed and the third step consists in replacing it. Vaseline or lanolin in which some antiseptic has been incorporated is rubbed into the scalp daily for from one to six weeks, then every other day for a similar time, then twice a week, and then once a week.

Chrysarobin is one of the best remedies in this condition. It is best applied in 6 per cent ointment with vaselin or lanolin as a base. It is applied daily for a week or two, then discontinued to see if the progress of the disease has been checked. If lanugo hairs do not appear, or if the hairs in the periphery of the patch can be pulled out easily the treatment should be resumed. This remedy should not be used near the eyes. The author asserts that lactic acid, 50 per cent in water or alcohol, gives good results. The affected parts are first freed from oil with alcohol or ether, then the remedy is applied on a swab till the skin becomes red. The following combination is useful:

B.	Thymolis	3ss	15
	Olei ricini		
	Olei amygdalæ dul., Rā	3ii	60
M.	Sig.	Apply to the scalp	

As recovery is often spontaneous, it is difficult to determine the exact value of the remedies used. Internally, arsenic, cod liver oil and similar tonics should be given when indicated, in connection with regulation of the diet and physical and mental hygiene. To prevent baldness the following may be used:

R	Pilocarpinæ hydrochloridi	gr v	33
	Olei rosæ	gr viii	50
	Olei rosmarini		
	Tincturæ cantharidis, aa	ʒss	15
	Glycerini	ʒi	30
	Olei amygdalæ dul	ʒii	60
	Spiritus camphoræ	ʒxxiv	96

M Sig Rub well into the scalp night and morning

In alopecia prematura, Stelwagon, "Diseases of the Skin," states that the patient's general health and the condition of the scalp must both be considered. Of general tonics he mentions arsenic, cod liver oil, strychnin, iron and the hypophosphites. The external treatment is the essential part. In cases in which eczema seborrhæum or seborrhea is present, or is the cause of the alopecia, treatment must be directed against this alone, and when this condition is removed the usual applications in uncomplicated cases of loss of hair can be utilized. One of the most valuable remedies is resorcin, but Stelwagon warns against using this drug, except cautiously, for patients with white or gray hair, as it stains the hair, giving it a dingy yellow tinge. Stelwagon recommends the following:

R	Resorcini	ʒi ii	4 8
	Olei tigli	m iv xx	20 1.33
	Olei ricini	m x xxx	05 1.90
	Alcoholis vel		
	Spiritus myricæ	ʒiv	120

M Sig Apply to scalp night and morning

In alopecia areata Stelwagon advises giving arsenic internally, in the form of Fowler's solution, in doses of from 3 to 5 drops (0.2 to 0.33) three times daily. Nux vomica and the iron tonics are also of value. Locally he prescribes the following:

R	Sulphuris precipitatus	ʒi ii	4 8
	Beta naphthol	gr xxx ʒi	2 4
	Adeps lanæ	ʒii	8
	Petrolati liq q s ad	ʒi	30

Ft unguentum Sig Rub well into scalp once daily

The remedial application should always be carried one quarter or one half inch beyond the border of the affected area.

If there are but two or three areas, Stelwagon states that the stronger remedies may be employed. Of these he recommends an ointment of chrysarobin, from 10 to 60 grains to the ounce of lard or vaselin, well and energetically rubbed in.

Hyde and Montgomery, "Diseases of the Skin," recommend the following formula:

R	Olei ricini	fʒss	15
	Phenol (acid carbolic)	ʒi	4
	Tincture cantharidis	fʒss	15
	Olei rosmarini	gtt xv	1
	Alcoholis q s ad	fʒiv	120

M Sig Apply to the scalp

Jackson has recommended a pomade made by boiling down a stated quantity of the fluid extract of jaborandi to one half its volume and adding to this four parts of lard. This is rubbed into the scalp twice daily. Jackson also recommends a lotion of corrosive sublimate gr 1½ (0.1) to the ounce of water, not on account of its parasiticide qualities, but solely on account of its stimulating effect.

All the preparations in common use in this condition possess both parasiticide and stimulating properties.

Heroin Addiction

Paul Duhem, in *Progrès Médicale*, calls attention to the fact that since the introduction of heroin, and especially since its employment in the treatment of morphin addiction, cases of heroin addiction have been observed in increasing numbers.

Duhem bases his conclusions on 16 cases of heroin addiction observed in connection with Sollier. Of these, three patients

acquired the habit from the use of the drug for asthma, four were morphin habitués who had used heroin in the hope of cure, three had first taken the drug for pain, while in six others the use was traced to various causes, such as fatigue, overwork, insomnia and other nervous symptoms which were added to a neuropathic constitution. The doses which were used as a remedy for asthma and other respiratory affections as well as those used as a substitute for morphin were rather large, 3 to 22 grains (0.2 to 1.5), while when used as an analgesic the amount was somewhat less, ½ to 1 grain (3 to 5).

The method of withdrawal of the drug was the same as that practiced by Sollier for the withdrawal of morphin. The patient is isolated and preparatory treatment instituted to stimulate the eliminative organs. Then the drug is withdrawn as rapidly as possible, ending in complete withdrawal in about a week, with constant supervision of the elimination, finally an abundant diet and tonic treatment are given. Contrary to the experience with morphin, it was found that to allow injections of heroin during the course of the withdrawal was accompanied by serious inconveniences. While morphin in minute quantity will restore a patient with slight cardiac defect, if he becomes prostrated during the withdrawal of morphin, patients addicted to heroin showed no such effect from injections of heroin. Duhem, therefore, concluded that it is best in case of heroin addiction to withdraw the heroin completely and to substitute morphin for it. This method suffices to prevent many accidents, but does not obviate the dangers altogether. The preference of heroin for the respiratory tract explains the frequency of attacks in which this function may be almost in abeyance. These attacks of respiratory failure occur in cases in which they may not be expected. From the moment of withdrawal the respiration and circulation are slowed and intellectual torpor is marked, there is marked sweating and a leaden type of countenance, but nothing indicates the imminence of the failure of respiration. The pulse is generally good, and if the countenance is not watched the attack may not be noticed until it is in full action. The breathing suddenly ceases, the face becomes pale, the eyelids tremble, the face becomes covered with a cold sweat and the patient loses consciousness. In addition to rubbing the limbs a double injection of ether and morphin should be given, the use of heroin is without effect in such a case. It is evident that heroin is removed from the system with much greater difficulty than morphin. The patients become very feeble and emaciated alarmingly. The normal functions are more slowly established and the convalescence is more tedious. While morphin users regain their lost weight at the latest at the end of the second week, those habituated to heroin require four weeks or more for the restoration of their original weight.

These considerations lead to the conclusion that morphin is to be preferred to heroin when an active narcotic is to be used, and that physicians should be on their guard against allowing patients to become habitual users of this drug on account of the greater injury which its habitual use entails and the greater difficulty presented in curing the patient of the degrading habit.

Gastric Sedatives

H B Sheffield, New York, calls attention to the fact that a highly irritated stomach will often reject even the most palatable medicine. Cracked ice cold or hot water, calomel or bicarbonate of soda, peppermint lime, or bitter almond water, small doses of bismuth and cerium oxalate, minute quantities of tincture of iodine well diluted in water, are all useful gastric sedatives. In continued vomiting of infants, lavage and advantageously supplants drugging.

When administering medicines to infants, it is often helpful to divide the regular dose, giving it, if need be drop by drop until the whole dose is consumed. In this manner the most irritable stomach will frequently retain the medicine when it would otherwise reject it.

Before prescribing any medicine the physician should always bear in mind the dictum "What is hateful to thee, do not unto thy fellow man."

Medicolegal

Duty Owed Injured Seamen.

The United States Circuit Court of Appeals, Third Circuit, says, in the case of *The Mars*, that the fact that a tug is engaged in comparatively short coastwise trips does not relieve her from the usual obligations of a vessel to her crew. One of these is to furnish, at the vessel's expense, care and maintenance to a seaman injured in her service. *The Osceola*, 189 U. S., 175. This right extends to a fireman. *The North America*, 5 Ben., 486. The word "cure" is used in its original meaning of care and means proper care of the injured seaman and not a positive cure, which may be impossible. *The Atlantic*, Abb. Adm., 451. The duty is to furnish means of cure and to use all reasonable efforts for that purpose. *Brown vs. Overton*, Fed. Cas. No. 2024. In the nature of things the end of the voyage does not end the obligation, if there was not sufficient time and facilities for the vessel to have then done its duty. Its unfulfilled obligation may continue after the voyage ends. *McCannon vs. Dominion Atlantic Company* (D. C.), 134 Fed., 702, *Henry B. Drake*, 141 Fed., 191, *The Svealand*, 136 Fed., 109, *Reed vs. Canfield*, 1 Sumn., 195. Neither the ancient codes nor the modern decisions show any reasoning or authority for holding that, where the injury to the seaman in the performance of his accustomed duties, was received through remissness or not unusual carelessness on his part, he thereby forfeits his right to cure and maintenance. *The Osceola*, *The City of Alexandria* (D. C.), 17 Fed., 395, *The Ben. Flint*, 1 Abb. (U. S.), 126.

Good Case Made Against Illegal Practitioner

The Supreme Court of Iowa affirms, in the case of the *State vs. Kendig*, a conviction of practicing medicine without a license. The indictment, found under Sections 2579 and 2580 of the Iowa Code, charged that "the said A. J. Kendig, on the 1st day of September, A. D. 1903, and from the said 1st day of September, A. D. 1903, until the time of the finding of this indictment, did, in the county of Madison and state of Iowa, falsely, wrongfully and unlawfully assume the duties of a physician and make a practice of prescribing and furnishing medicine for the sick, and did wrongfully, falsely and unlawfully publicly profess to cure and heal, without having first obtained from the board of medical examiners of the state of Iowa and filed for record, a certificate conferring on him the right to practice, contrary to the statutes in such cases made and provided."

The indictment was challenged on several grounds, and, first, that it was not sufficiently certain as to the person charged, or as to the offense intended to be charged, in that the act or omission charged was not set forth with sufficient particularity. It was said that the indictment did not give the slightest information as to the time, place or circumstances of the offense, nor of the evidence the defendant would be required to produce to establish his defense. But the court holds that here the statutory definition of the crime was complete, and, as the indictment charged the defendant's offense in the language of the statute, it was sufficient.

Again it was said that the indictment did not charge the defendant with prescribing medicine for, or practicing on, human beings, as distinguished from furnishing medicine for domestic animals. This objection, the court says, was purely hypercritical and without merit. According to the common understanding as well as in law, there is a distinction between the practice of medicine and the healing of the sick and the treatment of diseased animals.

Nor does the court think that the indictment was insufficient in that it did not negative the exceptions contained in the statute as that it shall not be construed to prohibit students from prescribing under certain conditions or gratuitous services in the case of emergency, etc. The court says that the general rule as to exceptions, provisos, and the like is that where the exception or proviso forms a portion of the description of the offense so that the ingredients thereof can not be accurately and definitely stated if the exception is omitted, then it is necessary to negative the exception or proviso, but where the exception is separable from the description

and is not an ingredient thereof it need not be noticed in the accusation, for it is a matter of defense.

That there was ample testimony to justify the verdict returned, the court explains by saying that there was no doubt that the defendant was visiting the sick, diagnosing their ailments and furnishing medicines for their cure. Not only this, but he filed claims against the estates of some of his patients for medical services rendered and asked the county to recompense him for treating a "county charge." The statute, the court further says, was intended to cover the advertising and selling of all medicines except those known as "patent" or "proprietary," and there was no testimony that the medicines which the defendant was vending belonged to either of these classes. Moreover, the defendant was not merely selling certain preparations, but he was visiting the sick and prescribing them for his patients.

By Whom Statutory Privilege May be Waived.

The Supreme Court of Minnesota says, in the case of *Olson vs. Court of Honor*, that Section 5662, Subdivision 4, of the General Statutes of Minnesota of 1894 provides that "a regular physician or surgeon can not, without the consent of his patient, be examined, in a civil action, as to any information acquired in attending the patient which was necessary to enable him to prescribe or act for the patient." It is manifest that the purpose of the statute is to protect the patient, and not his adversary, for the evidence may be received with the consent of the patient.

Does this privilege become absolute on the death of the patient, or may those who represent him or claim an interest under him after death waive the privilege for the protection of such interest? This is an important question, for if they can not waive the privilege given by the statute, and their adversary may invoke it to suppress the truth and defeat the enforcement of rights the deceased provided for them in his lifetime, then the statute may be made an instrument for cheating justice. If such be the proper construction of the statute, then, if an executor or legatee presents a will for probate which is contested on the ground that the testator was of unsound mind when the will was made, the executor or legatee may not, if the contestant objects, call the physician who was attending the testator at the time to testify as to his knowledge of the patient's mental condition, acquired in attending him. Nor could the personal representatives of a party, in an action to recover damages on account of the death of his intestate by the alleged negligence of the defendant call the physician who attended the intestate after his injury to testify as to the nature of the injuries and the cause of death, if such information was acquired in attending him.

Again, the case under consideration, the court says, illustrates the unreasonableness of such a construction. The defendant insured the deceased for the benefit of her husband and children against death by unintentional self destruction while under treatment for insanity. The best, and perhaps the only, evidence to prove that the deceased was under treatment for insanity at the time of her death was the testimony of the physician. Yet, if the statute was to be construed as the defendant claimed, then the plaintiffs, who were asserting a right under the deceased which provided for them in her lifetime, might not waive the privilege, but the defendant might invoke it to defeat the enforcement of their right. It can not be that such is the proper construction of the statute for it is unreasonable and unjust.

The adjudged cases, however, relevant to this question, are not in entire harmony, due, perhaps, to a difference in the wording of the several statutes construed. On principle and what seems to be the weight of judicial authority this court holds that the statute in question is for the protection of the patient, and he may waive the privilege if he sees fit, and that as a general rule those who represent him after his death may also waive the privilege for the protection of interests which they claim under him. In *re Will of Layman*, 40 Minn. 371, *Conates vs. Semper*, 82 Minn. 460, 23 Enc. of Law, 90, *Denning vs. Butcher*, 91 Iowa 425, *Winters vs. Winters*, 102 Iowa, 53, *Grand Rapids Ry. Co. vs. Martin*, 41

Mich, 607, Scripps vs Foster, 41 Mich, 742, Fraser vs Jennison, 42 Mich, 207, Groll vs Tower, 85 Mo, 249 It follows that the evidence of the physician in this case was competent

Insanity at Time of Trial and Expert Testimony

In the United States Circuit Court in Alabama, in *United State vs Chisolm*, an inquiry as to the sanity of a prisoner, the jury were told, among other things, that finite man at last gropes but darkly into the conditions of the human mind, and it is impossible for any court to lay down any fixed rule, as a matter of law, as to any particular state of facts which will unerringly demonstrate sanity, or the contrary condition of the human mind, or the degree of aberration which, when found to exist, exempts an accused person from criminal responsibility, or unfits him to rationally aid in his defense when arraigned for crime

But whether or not an individual's departure from general rules governing human action demonstrates such aberration of mind as exempts him from criminal responsibility, or shows unfitness on that account to be placed on trial, depends on the circumstances of the particular case, and is to be gathered not merely from the act for which he is arraigned, but must also be determined and tested in view of every other fact and circumstance which sheds light on the condition of the defendant's mind at the period as to which the inquiry is directed. Each particular case, therefore, presents a practical question, in the decision of which general statements of the theories of medical men and the reasoning of jurists furnish only partial, and sometimes little, if any, practical help

A person may be insane or partially so at one time, and subsequently be restored to sanity, and afterward be a responsible being in the eyes of the law. The reason why an insane person, or one who, though not insane, is laboring under such mental infirmity as to prevent his rationally aiding in his defense, should not be put to trial, is, in the language of the old books, "because he is disabled by the act of God" from making a just defense if he has one, and "because there may be circumstances lying in his private knowledge which would prove him innocent or his legal irresponsibility, of which he can have no advantage, because they are not known to persons who undertake his defense." Nevertheless, a person though not entirely sane, may be put on trial in a criminal case if he rightly comprehends his own condition with reference to the proceedings, and has such possession and control of his mental powers, including the faculty of memory, as will enable him to testify intelligently and give his counsel all the material facts bearing on the criminal act charged against him and material to repel the incriminating evidence, and has such poise of his faculties as will enable him to rationally and properly exercise all the rights which the law gives him in contesting a conviction

The defense of insanity, or mental inability to properly conduct a defense, is frequently resorted to without any just basis, and in passing on such questions the jury may give that consideration such weight as in their opinion it may deserve in connection with all the facts in the particular case. It would be a reproach to justice if a guilty man escaped the penalty for a crime on a feigned mental irresponsibility, or postponed his trial on a feigned condition of mind, as to his inability to aid in his defense. On the other hand, it would be likewise a reproach to justice and our institutions if a human being "made in God's own image," while suffering, as the old books put it, "under a visitation of God," were compelled to go to trial when he is not sufficiently in possession of his mental faculties to enable him to make a rational and proper defense. The latter would be a more grievous error than the former, since in the one case an individual would go unwhipped to justice, while in the other the great safeguards which the law adopts in the punishment of crime and the upholding of justice would be rudely invaded by the tribunal whose sacred duty it is to uphold the law in all its integrity

The jury is not bound by the opinions of experts. If the jury's common sense, reason, judgment and observation, in

view of all the evidence, produce the conviction in its mind that the expert is wrong in his opinions and conclusions, it may be governed by its own opinion and not by his. A jury should not capriciously or recklessly disregard the advice of medical men of experience in dealing with diseases of the human mind, and the advice of physicians as to such matters should be carefully weighed, but the final responsibility in arriving at a decision as to the mental condition of the prisoner rests on the jury. In this case all of the testimony of the medical experts seemed to agree that the prisoner had neurasthenia. One of them gave the opinion that he was suffering from incipient paresis. The name of the mental disease, if the prisoner was, in fact, suffering from such disease, was not important

In the absence of any proof on the subject, the law presumes that every ordinary being of mature age is responsible in all respects, and the government in prosecuting a defendant for crime is not bound to offer any evidence on that point, but may rest on the presumption. When, however, any facts are developed which go to rebut the presumption of responsibility, it becomes a question of fact in the particular case. While the force of the presumption of innocence until guilt is found beyond a reasonable doubt has no field of operation whatever in solving such an issue as that now submitted, yet the humanity of the law is such that no man should be considered a proper subject for criminal prosecution of whose ability to fairly and rationally make a defense there is just ground for reasonable doubt in the minds of the judge or jury which passes on that issue

1 Fracture Dislocation of Spine—Lloyd reviews the clinical history of fracture dislocation of the spine, and many of his views in regard to the treatment of his condition agree with those held by others. His previous papers on the same subject cover the ground fully. He has now performed laminectomy 32 times, and while some of his cases have improved to a marked degree, a very considerable number have shown absolutely no benefit from the operation. In none of the cases does he attribute the improvement to regeneration. He says that if regeneration of the cord does occur, more improvement would have followed in some of the cases in which no benefit was manifested. He says it is more than likely that there have been nerve fibers that were not destroyed and that have recovered their function, allowing for a more or less considerable improvement in the patient's condition. Spinal regeneration in the human species has not been proved, and therefore, it is fallacious to hold out this hope to the patient.

2 Id.—Bailey agrees with Lloyd in the matter of regeneration of the spinal cord. He says that in one third of the fracture dislocations of the spine, the cord escapes all injury. This is especially true in the cervical region. He says that the damage to the cord is that which takes place at once. Bailey does not believe that long continued pressure has much to do with it since if severely injured the cord shrinks and there is still space in the canal to hold it.

3 Id.—Haines says the treatment and expectant plan consists of extension and plaster jacket. If there is no evidence of recovery in the thoracic region, repleting the thoracic cut

ting But if the injury is in the thoracic region, or the cord is involved, it will be necessary to cut down on the laminae and spinous processes, open the canal, remove detached pieces of bone, or clots, arrest hemorrhage, and give drainage Even if the cord is not involved at first, unless an immobilizing apparatus is used, slipping of the vertebrae may cause or increase the injury of the spinal cord.

Haynes believes that, even if we can not diagnose the exact injury to the cord we should promptly open the canal and give the patient the benefit of the doubt, since pressure for some days will make permanent an injury that might be relieved by early operation Even when the cord has been entirely severed, a sort of repair goes on which improves the condition of the patient and enables him to live, while without repair death ensues under a year

4 Phototherapy in Nervous Diseases—Rockwell claims that, as a rule, whenever and wherever pain exists, whether in the form of the neuralgias or neuritis, or pain of the rheumatic or gouty type, a judicious application of the light bath is pretty certain to give temporary relief, and successive applications, in a large proportion of cases, are followed by permanent relief In the toxemias and the toxic neuroses the therapeutic value of light energy is beyond question The benefit derived from the light bath is often greatly enhanced by supplementary physical methods, such as static high frequency currents and general faradization

5 Early Mobilization After Gynecologic Operation—Brothers sums up his views as follows Early mobilization tends to overcome ordinary vomiting, accumulation of intestinal flatus, and bronchial irritation from retained secretions in the air passages Instead of contributing additional risks to the possibilities of thrombosis and embolism in the absence of septic infection, the early moving about of these patients actually tends to reduce these risks The morale of these patients is always wonderfully improved The total result is an earlier and more pleasant convalescence Brothers cites a number of cases in support of his views

6 Diazo Reaction in Tuberculosis—Williams always makes a careful and complete urinary analysis of every case of pulmonary tuberculosis, and the diazo reaction is one thing in particular that he always looks for, believing its presence or absence a valuable prognostic sign He says that the absence of the reaction in white patients is of favorable prognostic value In the colored patient, the absence of the reaction is of no prognostic value The presence of the diazo reaction in white patients is of unfavorable prognostic value Williams says that not only the fresh specimen of urine should be examined, but also one which had stood for twenty four hours

7 Subdeltoid Bursitis—That traumatism in one form or another is the usual cause of subdeltoid bursitis is shown by the four cases reported by Painter He says that the most common injury producing this condition is a fall on the shoulder or a violent twist or wrench of this articulation Painter believes that the treatment of all these cases should consist in open incision and removal of the entire sac irrespective of the duration of the case or the cause of the condition The after treatment, which is begun within a week or ten days, consists of passive motion and hot fomentations to the shoulder Painter found that the prognosis is better after the open method of treatment than after simple manipulation Convalescence is also much shortened and the functional results are considerably better

8 Surgery of Right Upper Abdominal Quadrant—Lund emphasizes the advantage of early operation in diseases of the stomach gall bladder and pancreas and the imperative necessity of early operation in perforations He says that pres-

ent diagnostic methods are inadequate, and therefore the surgeon must hold himself in readiness at all times to meet conditions different from those suspected before operation

9 Treatment of Neurasthenia—In the treatment of neurasthenia, Canfield considers it wise to begin at once with physical therapeutics, consisting of isolation, rest, over feeding, and exercise These remedial measures are followed up by psychotherapeutics

13 Essentials in Crusade Against Tuberculosis—The essentials in the crusade against tuberculosis are enumerated by Flick as follows 1 The control of contagion 2 The disinfection of infected places and things 3 Life in the open air 4 Proper food He says that so far as possible the work in a community should be led by private effort and supported by the government Education and the value of fresh air and proper food should be inaugurated everywhere and carried on in the school room, in the press, and on the platform He urges the establishment of sanatoria and convalescent farms for consumption, although he considers the hospital the most efficient for the prevention of tuberculosis as it removes patients from the community during the period when the disease is in its most contagious form

15 Physical Process of Immunity and Infection—This is the third paper by Wright on this subject In it he discusses the electro-dynamics of the surfaces of living protoplasm

16 Behavior of Eosinophiles in Pulmonary Tuberculosis—Swan and Karsner present further evidence of the behavior of the eosinophile leucocytes in cases of tuberculosis, with special reference to the prognostic value of these cells found in the peripheral blood Differential counts of the leucocytes in the blood of 31 cases of pulmonary tuberculosis were made Of this number, 26 cases were fatal and five were stationary, or were improving under treatment at the time the observations were discontinued In all the fatal cases except two the eosinophile cells were below 1 per cent as a rule, at periods varying from 102 days before death to the day of death In the cases which remained stationary or which were improving under treatment the eosinophiles, while subject to fluctuations, were present in fair proportion, usually over 1 per cent The authors conclude from their observations that in cases of pulmonary tuberculosis the eosinophile cells tend to disappear from the circulating blood as the progress of the disease brings the fatal termination nearer, and that as the patient improves under treatment and as the disease shows a tendency to become arrested, the eosinophile cells reappear in the circulating blood A full report of the cases studied is appended to the paper

18 Ear Disease and Mind Disease—The results of Bryant's experience in examination of the ears of the insane have convinced him that ear disease is much more prevalent among the insane than among the sane In fact, it is the exception not to have some demonstrable functional disturbance of the ear Bryant found it present in 90 per cent of the insane examined In many of these cases a history was obtainable which showed that the ear disease was in existence before the insanity appeared, and in others the condition of the ears was such that it must have antedated the mental disturbance

20 Ammonia to Counteract Fumes of Formaldehyd—Wilcox subscribes to the value and efficiency of using ammonia for the purpose of neutralizing formaldehyd In fumigating a sick room containing 1,500 cubic feet of space, two quarts of methyl

alcohol were consumed in a formaldehyd generator, and in addition three pounds of commercial formaldehyd were exposed on the sheets. As soon as the room had been ventilated sufficiently to make it possible to work in it, one and one half quarts of ammonia were sprinkled over the rugs and bedding, and the room was closed again. About the same proportion of ammonia was used throughout the other rooms of the house where the quantity of formaldehyd generated had been relatively somewhat less. The formaldehyd fumes were completely destroyed within one-half hour, and the odor could not be detected in any part of the house except where formaldehyd had been spilled on the floor and had left an incrustation of paraform on the woodwork. As soon as these spots had been treated with ammonia the odor of formaldehyd disappeared entirely.

28 Sarcoma of Long Bones.—The diagnosis, treatment and prognosis of sarcoma of the long bones are discussed by Coley, and he reports 69 cases. The great majority of his cases were treated by the routine methods now in vogue, namely, high amputation or exarticulation at the proximal joint. He has resected in no case. He performed amputation at the hip joint eight times without mortality, but four of the six patients in whom it was performed for sarcoma of the femur died within the year, the fifth in one and one-half years, and the sixth was not traced. In two the amputation was done for sarcoma of the soft parts. One patient died a year later and the other, who had received several months' treatment with the mixed toxins prior to amputation, now remains well after a period of six years. Coley has seen six cases of sarcoma in patients under ten years of age, one, a sarcoma of the humerus in an infant twenty months old, and four of the femur in patients aged seventeen months, six, seven, and nine years respectively. Amputation was done in 2 cases, disarticulation in 16, resection in 6, and in 29 no operation was done. Coley believes that the use of the mixed toxins of erysipelas and bacillus prodigiosus after operation will greatly widen the limits within which the operation of resection may be employed safely, even in the cases of more malignant sarcomas. All the cases are reported in full.

29 Anterior Thoraco-Bronchotomy.—In the case reported by Goeltz a metal collar button was inspired and lodged in the right bronchus. It was impossible to remove the button, except

by operation—thoraco bronchotomy—and this was done successfully. Forty eight hours elapsed between the inspiration of the button and its removal.

30 Surgical Treatment of Empyema.—In the method employed by Lloyd the opening in the chest is made in the usual way, the pleura is incised, and the accumulated fluid is allowed to drain away gradually at first. Ether is the anesthetic employed, and before opening the pleura the anesthetic is stopped in order that there may occur a sudden expansion of the lung, and that during the remainder of the operation the patient may be coming from under the effects of the anesthetic gradually. As soon as the fluid is drained away, the opening in the pleura is made sufficiently large to permit of thorough exploration of the pleural cavity and to locate the position of the collapsed lung. While the adhesions are being severed with the finger the patient begins to cough, owing to the sensitiveness of the pleura, and with each forced expiration expansion of the lung takes place until finally the lung fills the pleural cavity. Lloyd employs a drainage tube, which in appearance is similar to a spool. He has operated in 225 cases by this method. Of these, 97 patients were cured, 58 were improved, and 47 died (including the deaths from all causes and for all periods of time after the operation).

31 Cyst of Omentum.—Fort discusses 21 previously recorded cases of cysts of the omentum and adds one personal case.

32 Tuberculosis of Bladder.—In this paper Walker discusses the differential diagnosis, the prognosis and the treatment of tuberculosis of the bladder.

33 Drainage of Knee Joint.—Peck believes that drainage of the knee joint by the transverse incision has not received the attention it deserves. He says that the operation should not be employed in mild or early cases in which there is hope of recovery with some preservation of joint function, drainage and irrigation through multiple incisions being preferable. He insists that a distinction should be drawn between cases in which the crucial ligaments are preserved and straightening the limb without resection, resuturing the patella or its ligament and preserving some degree of function is the end in view, and in the severer cases where avoidance of amputation or death from sepsis are the sole considerations. He maintains that in the latter class of cases the complete operation is of great value and should, as a rule, be followed by resection as a secondary procedure, except in children. Flexion of at least 45 per cent. on a suitable splint is essential. The secondary operation should not be performed until suppuration has ceased, surfaces are cleanly granulating, and temperature is practically normal.

34 Diffuse Cavernous Angioma.—Ashurst adds one case to 11 other cases recorded in the literature. His patient was a little girl, 12 years of age, the tumor being situated on the extensor surface of the forearm just above the wrist. The front of the thorax on the right side was the seat of a nevus composed of dilated capillaries, and below the angle of the right scapula was a mass the size of a walnut. Similar masses were palpable in several other localities.

35 Fracture of Coracoid Process of Scapula.—Petty reports a case of fracture of the coracoid process of the scapula in a powerfully muscled man, 57 years of age. The shoulder was treated by dressing the arm in the Velpeau position, which subsequently had to be changed on account of the inconvenience it was causing and the right arm was bound to the side of the patient, leaving his forearm free. Later, light massage and passive motion were employed. At the end of the seventh week the patient was still unable to raise his right arm above his head.

36 Glanders.—Pilcher presents a detailed report of two cases of glanders occurring in the human subject. In one case the infection is believed to have occurred through inhalation and in the other case through a scalp wound. Both cases terminated fatally. In one case the incubation period was 25 days and the other only 5 days. In both cases the striking feature was the fact that the degree of prostration was greatly out of proportion to the physical signs. There was early involvement of the larger joints of the body.

41 Case of Rachischisis P Horowitz, New York
42 Value of Cystoscopy in Gynecology H D Furness New York
43 Surgical Treatment of Empyema S Lloyd New York

37 Urea Uric Acid Ratio—After a very careful study of the exact ratio between the output of urea and uric acid, Porter concludes that no fixed standard of proteid intake has been established and that no fixed composition of the urine exists. The main point to be determined is the amount of uric acid produced because it is a positive index to one form of suboxidation. Securing all the urinary analyses possible from different sources, adding them together and striking an average, gives a fair standard of nitrogen output by the kidneys. A similar method applied to the hepatic secretion and to other secretions and excretions gives the total daily output of nitrogen from the system. Securing the total output of nitrogen determines the amount of food that must be ingested and assimilated to insure the full quota of nitrogen in the excreta, etc. Uric acid must be classed both as a secretion and as an excretion, and in both instances represents proteid utilization. Porter says that faulty action of the liver often causes the toxic symptoms commonly classed as uremic, and especially so when there is an excessive elimination of nitrogen through the kidneys.

44 Traumatic Appendicitis—Out of 129 cases of appendicitis Black found three in which trauma was the direct cause, and one in which it served as an exciting agency. In the first three cases there was no history obtainable which in the slightest would suggest previous trouble with the appendix.

45 Cleft Palate.—Carmody reports a successful operation for cleft palate done on a young lady, 19 years of age. The Brophy operation was the one employed.

47 Perforating Gastric Ulcer.—In the case reported by Dixon the perforation occurred in the anterior wall of the stomach. It was closed with catgut sutures, 28 hours after perforation had occurred. The case was interesting further because of the absence of many symptoms which typical cases of gastric ulcer offer, if not usually present previous to perforation.

48 Controlling Hemorrhage in Cesarean Section.—The following plan of controlling hemorrhage under certain conditions was employed by Fleming. After having made the usual incision in the uterus the placenta was discovered attached to the anterior wall. In attempting to detach it so as to enter the cavity through the membranes, it was found that not only the placenta but the membranes were firmly adherent to the uterus. It then became necessary, in order to quickly deliver the fetus, to go directly through the placenta, which was done and the fetus delivered, cord cut between two forceps and the child handed to an assistant. The hemorrhage at this time was very profuse, both from the placenta and the incised uterine wall. The assistant could but partially control it by the usual method of pressure on the broad ligaments. Fleming grasped the uterus with both hands and quickly and easily inverted it through the incision, when the hemorrhage ceased immediately, after which the placenta and its membranes were carefully separated and removed, the uterus replaced and sutured.

49 Massage of Heart.—Freeman reports one instance in which massage of the heart failed to revive the patient, a

woman 38 years of age, who was being operated on for obstruction of the common bile duct by gallstones. The patient had been jaundiced severely for months and the operation was one of necessity rather than choice. She stopped breathing as soon as the abdomen was opened but was resuscitated by means of prolonged artificial respiration. Strychnin was used and physiologic salt solution was injected during the operation. While the wound was being sutured the patient's breathing again ceased. Artificial respiration, continued for ten minutes, resulted in failure. Meanwhile the cardiac impulse had stopped and heart massage was resorted to, but also proved ineffective.

53 Mammary Sarcoma.—Miel cites a case of sarcoma of the breast occurring in a colored girl, 16 years of age. The tumor was removed and after six years there is no evidence of recurrence.

57 Complications of Labor.—The conditions discussed by Reder are unusual rigidity of the soft parts, a want of correspondence of axis caused by obliquity of the uterus, and a mechanical obstruction of the os by a scar, the result of a trachelorrhaphy performed five years previously.

58 Acute Fever in Childhood.—Zahorsky refers to an acute infection of the urinary tract, occurring especially in girls, which gives rise to an acute fever of varying duration and intensity and which is often overlooked. He has seen nine cases. The fever resembles that of typhoid, but it is dependent on an infection of the urinary tract. A remarkable feature of these cases is the slight disturbance of the bladder.

60 Orchitis in Typhoid.—Gwyn reports two cases of typhoid in which orchitis was a complication. In the first case the onset of the orchitis was marked by a severe abdominal pain in the appendiceal region, with marked distension, slight rising pulse and temperature, but no leucocytosis, muscular rigidity or signs of collapse suggesting perforation. Following this the testis on that side became enlarged. The swelling subsided quickly the pain disappearing by the fourth day. This case is of interest in that it gives another clue to the origin of some cases of abdominal pain in typhoid. In the second case the orchitis occurred during the fifteenth week. The pain in the testis and groin was most severe the gland rapidly swelled to the size of a goose egg, constitutional disturbance was marked. After a week the organ suppurated and the abscess broke through the scrotum. Gwyn says that evidently this was a case of direct typhoid infection in the testis.

61 Pre Icteric Itching—Riesman reports three cases of jaundice in which itching was the first symptom, showing that the itching is not due to a deposit of bile pigment in the skin, but in all probability is caused by some metabolic poison. Riesman suggests that when itching exists for which no cause can be found, the liver as a possible factor should not be overlooked. He says that pre-icteric itching is suggestive, though not pathognomonic of the existence of malignant disease involving the liver or the biliary passages.

67—See abstract in *THE JOURNAL*, Jan 13, 1906, page 149

60 Congenital Fetal Malformation.—In the case reported by Barnes two inches of the duodenum were replaced by a small impervious fibrous cord. Below this cord the intestine was abnormally small for a short distance and then shaded into a normal bowel. The child died of exhaustion at the end of 72 hours.

73 Infantile Scurvy—Brown gives the histories of five cases of infantile scurvy observed by him. One of the cases terminated fatally.

75 Prevention of Tooth Decay—Low discusses briefly the report of the committee on scientific research of the New York State Dental Society in which is recommended the administration of potassium sulphocyanate in one grain doses, before retiring at night, for the prevention of tooth decay. This commission found that in mouths where rapid and general decay of the teeth exists, potassium sulphocyanate is absent, whereas this salt is present in large quantities in the mouths of individuals whose teeth are immune to decay.

82 Purulent Conjunctivitis H. McKee Montreal

80 Miliary Tubercle of Choroid.—Mathewson reports two cases which present some interesting features. The first case was diagnosed as a pleurisy with effusion, and a considerable quantity of fluid was removed. An examination of the fluid and also of the sputum for tubercle bacilli proved negative. A guinea pig was inoculated with some of the pleural fluid and when killed showed definite signs of tuberculosis. A careful examination of the eyes revealed two miliary tubercles of the choroid in the left eye. The patient died with pronounced symptoms of meningitis. A necropsy could not be done. The second case presented the characteristic symptoms of typhoid including a positive Widal reaction, but the period of elevated temperature was unduly prolonged. The patient began to complain of headache, cough and scanty expectoration. Examination of the sputum for tubercle bacilli was negative. An area of slightly impaired resonance was found at the apex of the right lung. In each eye there was a single miliary tubercle. The patient died and the necropsy showed miliary tuberculosis of lungs, liver, kidneys, meninges and choroid.

87 Salt Action and Salt Solutions A L Muirhead Omaha

85 How to Check Commission Evil—In Gifford's opinion there are two measures that would, in a measure, check the commission evil. One of these would be for the state or national society to come out flat footed and say that the best way for the general practitioner to get his dues is to establish a rule that he is entitled to a definite share, say 10 per cent. or

25 per cent, of the fee charged by the specialist, and that this share shall be paid with the full knowledge of the patient, and that any one paying or offering to pay a larger commission than the established one shall be expelled from the society. Such a plan, objectionable as it might be on some grounds, would at least have the merit of being free from hypocrisy. Its most serious defect, however, is that it would inevitably lead to one of the abuses which any system of commission giving leads to, namely, to the sending off of a lot of patients for operations or consultations which could well be avoided. The other measure, and the one which Gifford seriously proposes for consideration, is a rule which shall automatically expel from the society any member who, after a fair and impartial hearing shall be found guilty of giving or taking commissions.

93 *Simple Test for Convergence Power M D Stevenson Akron Ohio

88 Inner Pole Magnet—Gifford questions whether the inner pole magnet can excel or even equal the strength of the Haab instrument, but his experience has convinced him that the instrument possesses advantages which make its use desirable. These advantages are the ease with which the eye can be illuminated when the small points are used, and the handiness of the small cores in comparison with the giant magnet or any hand magnet. Where a maximum of magnetic force is desired, the Haab instrument, used as an inner pole, is the ideal one.

92 Pulsating Exophthalmos.—Lewis' patient was a strong man, 26 years old, who received a blow on the head, which rendered him unconscious. After several weeks a pulsating exophthalmos was present. A marked feature of the case was a feeling of anxiety almost amounting to nervous terror. Having decided that an aneurism of the ophthalmic artery was responsible for the condition, Lewis concluded to operate. The artery was tied off just within the orbital cavity and within three weeks all the symptoms, except some divergence, had disappeared. The patient eventually made a complete recovery. Vision in each eye was 20/30. The interest in this case centers in the fact that although some portion of the aneurism extended outside of the orbit, a ligature within succeeded in controlling it, and that without removal of the eye.

93 Test for Convergence Power.—The test described by Stevenson is used to ascertain whether a patient's eyes converge just enough, too much, or too little for an object held one third of a meter from the eyes, while the desire for single vision is suppressed.

2 *Treatment of Incipient and Borderland Cases of Insanity in General Practice E. W. White
3 *Case of Abscess of Cerebrum Recovery L. B. Rawling
4 *Total Enucleation of Prostate, for Radical Cure of Enlargement of that Organ P. J. Freyer
5 *Tetanus Treated with Antitetanic Serum M. W. Hall, E. G. Carter and C. R. Howard.
6 *Staining of Animal Parasites I. W. Hall.
7 Kala Azar L. Rogers

1 **Friedreich's Ataxia**—Griffith reports five cases of this affection occurring in two families. In one family two sisters, aged respectively 17 and 10 years, were affected, and in the other family the second, third and seventh members of a family of 13 were affected. These three patients were two brothers, aged respectively 20 and 18 years, and a sister, aged 27 years.

2 **Incipient and Borderland Cases of Insanity**—The cases considered by White in discussion of treatment are the following: Backward or deficient children, epileptics, neurotics, the moral imbecile, incipient melancholia and mania, borderland delusional cases, the premature demented, borderland alcoholic insanity and paralytic insanity, incipient senile dementia, and the incipient general paralysis of the insane. The treatment adopted by White is similar to that employed by other alienists.

3 **Cerebellar Abscess**—Rawling reports a case of abscess of the cerebellum, occurring in a man aged 21, who had been suffering from a purulent discharge from the left ear for four months, pain in the ear then developed, and two weeks later chronic frontal headache. There also was inability to close the left eye completely, and the face was drawn over to the right side. The mastoid antrum was exposed and found full of cholesteatoma. The extradural space was exposed and examined, but without result. Although the patient felt better afterward, the previously existing optic neuritis increased and vomiting of the cerebral type occurred. At a second operation the antero-lateral aspect of the cerebellum was exposed and an abscess cavity was found one inch from the surface. One ounce of greenish pus was evacuated and the cavity adequately drained. The patient regained excellent health, but complained of pain over the left occipital parietal region and of inability to see objects in the right visual field. The gait was also slightly staggering and there was a decided tendency to lurch toward the left side when standing with the eyes shut. There was no evidence of optic atrophy.

4 **Enucleation of Prostate**—Freyer reports a further series of 119 enucleations of the prostate for enlargement of that organ, making a total of 309 cases in which he has operated. In connection with these 119 operations there were nine deaths. The causes of death were jaundice (case complicated by malignant disease of liver), pulmonary embolism, shock and uremia (six cases in which the kidneys were extensively diseased before operation). The ages of the patients varied from 50 to 86 years, the average age being about 68.

5 **Tetanus Treated with Antitetanic Serum**—Hall, Carter and Howard each report a case of tetanus successfully treated with antitetanic serum.

6 **Staining of Animal Parasites**—The method of staining animal parasites devised by Hall is described as follows:

- 1 Prepare a film of the blood feces or sediment of the secretion. Fix by heat, or less preferably by formalin vapor.
- 2 Treat the film with the following solution from one-half minute to 2 minutes: Watery methylene blue 1 per cent, 100 c.c.m. glacial acetic acid 5 c.c.m. (Nissler's methylene blue solution may be equally well used if at hand. Methyl violet, Nile blue, etc. are not so good).
- 3 Wash in water.

4 Cover the film with saturated alcoholic eosin solution. Allow to stain for from 5 to 10 minutes, or heat over the flame, blowing out the alcohol each time it catches fire, until the film is almost dry.

5 Wash in water.

6 Fix in potash alum solution for from one-half minute to 2 minutes.

7 Decolorize in 90 per cent. alcohol until a uniformly pink color obtains.

8 Wash in water, allow to dry, mount in Canada balsam.

It is the treatment with acetic acid which affects the outer coverings of the ova, embryos and parasites, and allows the stain to permeate the entire structure.

10 **Insanity**—Of 110 alcoholic cases investigated by Urquhart nearly 43 per cent were hereditarily predisposed to insanity, and nearly 23 per cent to alcoholism. Out of 40 cases of general paralysis 23 were undoubtedly syphilitic and 14 were alcoholic. The author's experience leads him to believe that the hereditary factor is of importance in general paralysis. Among his 40 cases the heredity of insanity found expression 10 times, eccentricity 4 times, neurosis 12 times and alcoholism 14 times. Rheumatism, gout and tuberculosis were also noticed. There was a distinct neuropathic heredity in 32 cases. There were only five cases of ordinary, uncomplicated epilepsy and 11 of alcoholic epilepsy. Urquhart concludes that the innate or hereditary cases of insanity terminate in recovery in fair proportion, although they are more subject to relapse than cases in which the insanity is acquired. He finds that the average age on admission for men is 36 years, and the age of death 54.65 years, as against 63.96 for healthy males. The average age on admission for women is 38 years, and the age of death is 60.93, as against 66.83 for healthy females. Of 800 patients 31.14 recovered, in 38.93 the condition remained stationary, 17.3 died.

12 **Observations on Uterine Fibroid**—Giles claims that the doctrine that the menopause is Nature's cure for fibroids is a mischievous tradition. He summarizes his reasons for this belief as follows:

1 The ostensible menopause is delayed in cases of fibroids and menstruation—or, at least, uterine hemorrhage—may continue for years after the usual age of the menopause has been passed. Meanwhile the severe losses of blood may imperil the patient's life, or impair her health so seriously that many years will be required to recover the lost ground.

2 The cessation of hemorrhage when it does occur does away with only one of the dangers incidental to fibroids, and the patient may remain for many years disabled by pain and by the weight of the tumor.

3 The time of the menopause has its own special risks in relation to fibroids, the most important are degenerative changes in the tumors and injurious pressure effects when a tumor which has occupied an abdominal position atrophies just sufficiently to allow of its falling into and filling the true pelvis.

4 When in the vain hope that the menopause is going to work a cure operation has been delayed year by year and then has to be undertaken in spite of complications and of the enfeebled state of the patient, the danger of a fatal result is materially increased.

17 *The Actinic Theory of Sunstroke A. Duncan

16—See THE JOURNAL, Dec. 22, 1906, page 2087

17 **Actinic Theory of Sunstroke**—Duncan believes that the actinic theory of sunstroke is the correct one. He urges that soldiers' helmets should be lined with orange red, that their khaki coats should have a detachable strip of orange red underneath the material along the spine, and that the men should wear shirts dyed this color.

Intercolonial Medical Journal of Australasia, Melbourne

January 20

- 18 Malaria Disease W. Summons
19 *Case of Acute Suffocant Pulmonary Edema A. L. R. White
20 *Acute Hemorrhagic Pancreatitis R. H. Russell
21 *Cases of Surgical Interest W. Moore

10 Acute Suffocative Pulmonary Edema—The treatment employed by White in his case proved most effective. Nothing was known of the history of the patient, a man except that he had vomited several times on his way to the hospital. He was given strychnin and inhalations of oxygen and amyl nitrite without any apparent relief of the dyspnea or any lessening of the degree of cyanosis. He was then given morphin, gr 1/6, with atropin, gr 1/100, and in about ten minutes improvement in his condition was noted. Fifteen ounces of blood were then extracted from one of the veins of the forearm. During the venesection the patient rapidly improved and regained consciousness. The man was kept in bed, dieted and given potassium iodid in doses of from 20 to 30 grains, three times a day. He recovered from this attack, but about five months later he returned with another attack. The same treatment was carried out as before, with the same result.

20 Acute Hemorrhagic Pancreatitis—Russell reports an instance of this kind, which simulated intestinal obstruction so closely that the diagnosis was made accordingly. Operative intervention carried the case to a successful end.

21 Cases of Surgical Interest—The cases reported are as follows. Two cases of appendicitis in which the omentum was wrapped around a sloughing appendix, two cases of fracture of the femur, with fracture of the upper end of the humerus.

Glasgow Medical Journal March

22 *Ankylosis of Spine. W. K. Hunter

23 Value of Tuberculo-Opsonic Index in Diagnosis. E. T. Fraser

24 *Case of 'Spider's Lick'. D. H. Macphail

25 *Fracture of Rib by Sneezing. H. E. Jones

22 Ankylosis of Spine—The outstanding feature of Hunter's case, a man aged 48 years, was the rigidity and immobility of the vertebral column, but associated with that was a generalized muscular atrophy as well as contractures of the adductors of the humerus and the flexors of the knee. He regards the case as one of rheumatoid arthritis.

24 Spider's Lick—Macphail reports a case of eruption on the forearm due to contact with a spider. The whole of the affected area was red and raised above the general surface. There were numerous small pustules. There was no pain. Itching was present at first, but soon disappeared. A carbolic acid dressing, 1:40, was applied and on the following morning the eruption had disappeared. In India this condition is known as spider's lick.

25 Fracture of Rib by Sneezing—Jones reports a case of fracture of the tenth rib, which the patient thought was the result of a very violent sneeze. No other cause for the fracture could be discovered.

26 Treatment of Experimental Trypanosomiasis—This article relates the results of extensive experimental research on trypanosomiasis induced in rabbits, dogs, monkeys, etc. and treated with various stains and a preparation of arsenic. The writers do not state that any of the numerous animals in their experiments were cured by the drugs, but they add that such is their impression in regard to the monkeys and to the majority of the rats and other animals. [Ehrlich has recently announced that trypanosomes gradually acquire an artificial immunity to certain drugs when treated with them for some time. He was able to demonstrate this for 18 different chemicals belonging to the trypan group, the arsenic group and the basic anilin stain group, producing fuchsin proof, trypan red proof and a number of other similar strains of trypanosomes. This acquired property of artificial

immunity to a certain chemical was retained by one strain through 92 passages through animals. He found further that when a strain had become thus immunized against a certain chemical, another chemical might be able to act on it with primal power—in case sufficient amounts were used—and the trypanosomes would be rapidly annihilated. He draws the conclusion that a combination of some of the various remedies from these three groups of chemicals found effectual against trypanosomes might cure the trypanosomiasis where a single one would fail. Laveran, van Campenhout and Kopke have also reported experiences showing the advantage of combining strychnin with arsenic in treatment of sleeping sickness.—Ed.]

30 Ocular Manifestations of Trypanosomiasis—Morax calls attention to the frequency and the special characteristics of the ocular manifestations in the course of infection with trypanosomes. The finding of an interstitial non ulcerative keratitis, in an animal, suggests the possibility of a trypanosome infection. This interstitial keratitis is the work of the trypanosomes proliferating in the spaces between the layers of the cornea. Their proliferation induces infiltration of leucocytes and may entail complete disorganization of the cornea, or the lesions may heal, leaving scarcely a trace. The latter condition is observed in animals that display marked resistance to trypanosome infection. This was observed particularly in goats infected with dourine or nagana. Dogs, on the other hand, always died while the cornea was still completely opaque.

33 Program for International Congress of Penology—The French government commissioned the Académie to suggest topics for discussion at the next international congress of penology, to be held at Washington in 1910. The committee to which the matter was entrusted suggests three topics. "The advisability of adding to the law course a course on elementary psychiatry to enable lawyers and judges to be better equipped for passing judgment on the criminal in sane. Physicians of penal establishments should be thoroughly trained in psychiatry, to enable them to estimate the mental condition of the prisoners in their care. Systematic surveillance by an expert psychiatrist would disclose the cases of insanity developing in the prison, and enable their cure by treatment in appropriate institutions, and it would also supply a basis for rectification of errors in judgment and the revision of sentences imposed on the irresponsible." The second question suggested for discussion is "The advisability of creating special establishments, intermediate between the prison and the insane asylum, in which criminals can be interned when there is doubt as to their mental responsibility, the duration of their stay in the establishment to be determined by the improvement in their mental condition. They should not be discharged without a legal decision to that effect based on the advice of a special committee." The third question refers to the advisability of complete suppression of all alcoholic drinks in case of convicts addicted to alcohol.

34 Severe Gastrointestinal Infection from Oysters—An epidemic of 125 cases of severe gastrointestinal disturbances is described, traced to infection from oysters. The cases were distributed through fourteen towns. All the persons affected had partaken com.

ters from a certain oyster bed. In 33 persons typical typhoid fever was observed, ending fatally in 7. In other cases a hectic fever simulated acute tuberculosis. Even when the disturbances were limited to colic, diarrhea and vomiting, they did not occur at once, but an interval of from 24 to 48 hours elapsed. In some cases there was much somnolence, weakness, and, especially in children, a syncopal condition with profuse sweating. Epistaxis was observed in many instances. The gastrointestinal disturbances generally subsided in a few days, but in some cases they persisted for several weeks and the patients were long in recovering. In 3 of the cases a choleraform diarrhea with anuria proved fatal. The troubles observed were evidently due to mixed infection. In 1896 the Académie recommended that all oysters from suspicious oyster beds, a week before being offered for sale, should be transferred to some point along the coast, where they would be laved with pure sea water, not so much for the purpose of rinsing the oysters as to promote phagocytosis, and thus to cause the destruction of micro organisms lurking in the oyster organism or their expulsion in the excreta or by the action of the ciliated epithelium. The vital processes in the oyster in contaminated waters are sluggish, but they start up with amazing energy when the oyster is transferred to pure sea water.

35 Fire-Damp and Carbonic Oxid.—Grehan urges that the air in mines should be tested for the presence of fire damp night and day, and has devised a simple means for determining its presence with the "eudiometer," slightly modified. He also calls attention to the extreme toxicity of water gas, stating that 22 c.c. of dry carbonic oxid were obtained from 100 c.c. of red blood from the inferior vena cava of a dog which had died in 33 minutes after breathing a mixture of 204 liters of pure air and 6 liters of water gas containing 40 per cent carbonic oxid. In another experiment, a dog was made to inhale a mixture of one liter of illuminating gas in 200 liters of ordinary air for an hour. About 28 c.c. of carbonic oxid were obtained from 100 c.c. of the animal's blood afterward. This experiment shows the danger from leaking gas fixtures, as 1 per cent of gas in the air caused the passage of nearly 3 c.c. of carbonic oxid into 100 c.c. of blood. Water gas, he says, contains seven times as much carbonic oxid as ordinary illuminating gas.

37 Suggestions for New Nomenclature for Diseases.—THE JOURNAL, March 2, 1907, p. 838, mentioned Lancereaux's suggestions in regard to a new classification and nomenclature of diseases. A committee was appointed to study the subject, comprising Lancereaux, Blanchard, Jungfleisch, Reclus and Pernet. The committee accepted Lancereaux's 3 classes and added 2 more, the "psychonoses"—affections caused by moral or mental agents, and "trophonoses"—affections caused by agents of nutrition. All diseases can be classified in these 5 groups. Physical agents—physinoses, chemical agents—cheminoses, animate agents—bionoses, mental and moral agents—psychonoses, and nutritional agents—trophonoses. The latter group includes all the affections resulting from nutritional disturbances, whether due to excessive or defective nourishment, insufficient or ill regulated physical exercise or vitiated air. These diverse causes induce a dyscrasia of the blood and organic lesions which may develop at almost any point, causing changes in the vascular or digestive system, in the liver or kidney, in the central or peripheral nervous system or plethora and vitiation of the blood. They are not only the direct causes of various diseases—gout, chronic rheumatism, diabetes, kidney and gallstones and sclerosis of the viscera—but they impress a special stamp on accidental affections of various organs which may supervene on a soil thus modified by the diathesis inherent to the individual. The rôle of the nervous system in some of these trophonoses is undeniable, but the trouble in the nervous system is a result of the general or partial dystrophy. This same diathesis is also responsible for certain hypertrophies or atrophies, arrests of development, deformities and tumors resulting from local nutritional disturbance, such as cancers, fibromata, lipomata and certain cysts. The term "pathy" the committee adds should be retained to designate the local manifestations of any of the

above 5 groups of agents, and if the adjective designating the cause is added, the term thus becomes explanatory while localizing the trouble, as, for example, syphilitic dermatopathy, alcoholic gastropathy, rheumatic cardiopathy. The advantages of a new nomenclature based on the above principles are extolled by the committee, and especially the tendency to direct the mind constantly toward the etiology of the affection in question. When the etiologic conception of an affection is constantly impressed on the mind it bears fruits in the lines of prophylaxis, of hygiene, both moral and material, and of treatment. Blanchard added that in parasitology an etiologic nomenclature has already made great progress. He has long used the terms "zoösis" and "bacteriosis" to take the place of mycosis and similar terms. Uncinariosis and babesiosis are proper terms, he declares, for the affections incorrectly called ankylostomiasis and piroplasmosis (the latter due to the *Babesia bovis*). The latter terms were introduced long after the others had been established in the literature and had proved their correctness and usefulness.

39 Malaria in Madagascar.—It is stated that malaria is more prevalent in Madagascar than ever before, and that the condition is becoming serious. It is impossible to petrolize the rice fields which are the main source of support for the natives, and it is equally impossible to screen the native huts. Blanchard urges the government to distribute quinin and to insist that all workmen on public or private works must take a daily preventive dose, given by the proprietors or contractors of the works, who should be supplied with quinin at cost price by the government. It is stated that out of a population of 35,000, Tananarivo had 18,000 ill with malaria last June.

40 Imaginary Seasickness.—Regnault has had much experience as ship physician, and points out the necessity for differentiating between actual somatic seasickness, and that which is exclusively the work of the imagination, as prognosis and treatment differ for the two forms. As a rule, in the imaginary variety the symptoms are more pronounced and more persisting. They may be accompanied by some unusual symptom which gives the clue to the imaginary character of the affection, sometimes the two forms are associated. It has been said that the smell of the ship, the sight of the movement of the ship and waves, and the noises of the machinery are the causes of seasickness, but the fact that the blind and deaf and those who have lost the sense of smell are liable to suffer from seasickness, shows that persons affected by these conditions suffer more from their imagina-

tion than from the reality. This is also the case in the sea sickness that comes from seeing others affected. Patients with imaginary seasickness require entirely different treatment from the other variety, emphasizing the psychologic element. These are also the cases that call for the most sympathy and in which the condition has hitherto been deemed incurable.

41 Communication Between the Auricles.—Rogers describes 2 cases of what he calls insufficiency of the interauricular valve. So long as the pressure in the left auricle is higher than that in the right, the valve keeps the abnormal opening closed, and the two auricles are separate and independent. But when the pressure in the right auricle is higher than that in the left, the valve opens and the venous blood mixes with the arterial. He diagnosed the condition in one case as nothing could be found in the heart or lungs to explain the excessive cyanosis and asphyxia. The patient was a man of 44, subject to recurring bronchitis every winter, rapidly inducing asphyxia and cyanosis. After the age of 30 he noted that he "got out of breath" easily on slight exertion, but was otherwise healthy. In the second case a man of 54 presented intense cyanosis accompanying recent bronchitis after old emphysema. As the bronchial affection healed, the cyanosis subsided. It reappeared, however, for a few minutes after every violent effort or fit of coughing. Each time that the insufficiency recurs in such cases the restoration to normal is slower and less complete.

50 Hygiene of the Table.—Labbé discusses the hygiene of the table and advocates four meals a day. Breakfast, he says, should be a warm, substantial meal to repair the tissues and produce energy for the morning's work. At noon, a light, easily digested lunch should supply the energy needed for the afternoon's work without making such demands on the system as to interfere with muscle and brain work. At 5 o'clock another light meal should be taken, supplying energy while waiting for the last meal of the day. This, the dinner at 7 or 8, should not be an elaborate meal, but a simple and short repast. As work is over, and as the expenditure of heat is less at night than during the day, the dinner does not have to produce much energy, but should serve merely for repair of tissue. The lightness of this repast enables the individual to retire soon after, without interfering with digestion or having his sleep disturbed. Labbé recognizes that this arrangement of meals conflicts with customary usages in France, but the first duty of the physician who strives to inculcate the principles of alimentary hygiene is to warn against habitual table excesses, and the present three or two meal a day plan generally leads to overeating at one or more of the meals.

56 Electric Sleep.—This is the term applied by Leduc to a condition in which all sensation is abolished and the individual lies in complete lethargy as the consequence of the passage through the brain of an electric current. The current used differs from those usually employed, in that it is constantly interrupted, a special device—of which he gives an illustrated description—allowing the current to pass, then interrupting it for a period nine times as long, then allowing it to pass again, always in the same direction, a hundred interruptions being made in the course of a second. The electromotive force should not be much above the low maximum desired, which renders storage batteries better for the purpose than the urban electric light service. The peculiar properties of this interrupted current, he states, have shown that it is far superior to all other means for exploration of the sensation, excitability, contractility, etc., in physiologic and pathologic conditions. Its proper use in these lines, he is convinced, will soon be rewarded with an abundant harvest of new facts. When this electric current is gradually turned through the brain of a dog or other animal he passes gently, progressively, and without a sign of resistance or pain, into a condition of cerebral inhibition analogous to the sleep of chloroform. Except for the preservation of the reflexes, especially if the spinal cord is not in the path of the current, the animal does not react to any stimuli, but seems to be in a condition of absolute general anesthesia, all kinds of oper-

ations can be performed and no reactions are observed any more than with profound chloroform anesthesia. To induce this electric sleep in the rabbit from 6 to 8 volts are necessary, giving 1 or 2 milliamperes in the intermittent circuit, which corresponds to 10 or 20 milliamperes in a circuit without the interruptions. The moment the current is turned off, the animal gets up, looks tranquilly around, manifesting neither suffering, fatigue nor fright, and as soon as he is relieved of the electrodes he frisks about gaily and eats with relish. No by-effects were ever observed, no vomiting, and only rarely a slight degree of stupor. The dogs submitted to the maneuvers without fear or resistance, even when repeated again and again. The action of the heart and lungs continues unmodified, even when the passage of the current is continued for nearly 5 hours, as he shows by tracings taken before, during and after such experiences. The instantaneous cerebral inhibition caused by closing the circuit always induces in animals the evacuation of the intestines and bladder. The blood pressure is high during the entire experience. This form of current abolishes first the functions of the higher centers, and not until later those of the heart and respiratory organs. For this reason Leduc thinks that this form of current would be much more humane than those usually employed for electrocution. Only two experiments on man have been made with this new interrupted current, and both were on Leduc himself, the results confirming in every respect those anticipated from observation of its workings on animals. The inhibition first affected the centers of speech, then the motor centers, the limbs without being completely relaxed were not stiff. The pulse was not affected, but respiration was a trifle impeded. When the current had been turned on to the maximum he was conscious, as in a dream, of what was going on around him, and could perceive contact, but with deadened sensation. The consciousness of the dissociation and successive suppression of the various faculties was like the impression in a nightmare in which one is unable to speak or move in the presence of a grave danger. On both occasions the experience was not pushed to the complete suppression of all consciousness, his assistants thinking each time that this stage had been reached, when they were just short of it. The voltage was 35, the milliamperage 4, and each time he was under the influence of the current for 20 minutes. When the current was turned off the awakening was immediate and complete, leaving no by effects except a sensation of physical vigor, so that he was able to proceed at once to deliver a lecture. It is possible also with this current, he says, to induce complete local anesthesia, so that with the eyes shut it is impossible to say whether the region is being pricked, pinched or cut. Using a more powerful current, he was able to induce a typical epileptiform convulsion in animals. About 55 volts accomplished this in the rabbit, but 110 volts were necessary for dogs.

- 66 *Diagnosis of Carcinoma of the Stomach (Diagnose des Magenkarzinoms) A Zirkelbach

62 Achyilia Gastrica.—Lieferschütz announces that in his test the secretion of the stomach in persons who have passed their fiftieth year showed a marked tendency to diminution. He states further that complete absence of free hydrochloric acid is relatively not a rare phenomenon in old age. In investigating the digestive power of the gastric juice by the

method of Mett, it should always be tested both without and with the addition of hydrochloric acid. The digestive power in cases of achylia produced by carcinoma of the stomach is not improved by the addition of hydrochloric acid. The aspect of the stomach contents and of the filtrate is often instructive. He adds that in examining the stomach contents the possibility of the passage of the so called natural mixture, that is, a mixture of intestinal juice, pancreatic juice and bile, into the stomach must be kept in mind. The occasionally observed presence of pancreatic juice in the stomach affords a new means for the study of pancreas digestion and its disturbances. Gastric digestion is far from being so simple as it might have been assumed from previously known facts. There is no reason, he says, for separating simple achylia gastrica as an independent clinical entity with definite etiology. Its origin should be determined in the interests of effective treatment as well as in reference to prognosis.

63 Action of Alcohol.—Kast concludes as the result of experiments on a dog after the method of Pawlow and on a girl with a gastric fistula, after resection of the esophagus, that alcohol increases the amount of gastric juice, but does not affect the percentage of HCl, while the amount of pepsin is reduced. In a strength of 10 per cent, or less there is no noticeable local irritation from the alcohol, but when the proportion is above 20 per cent local irritation is pronounced. Continued use of dilute solutions produces at first hyperchlorhydria, then catarrh with gradual decrease of acidity. The occurrence of hyperchlorhydria is explained by the fact that the increased quantity of the secretion mixed with the food gives an increased average acidity. In his experience, alcoholic drinks containing less than 20 per cent. of alcohol favored motility and absorption, and did not materially reduce peptonization.

65 Ulcer of the Stomach.—Tecklenburg concludes from his research that a number of relapses in case of gastric ulcer are due to overstretching of the walls of the stomach. The most important cause of this overdistension is muscular atony and the swallowing of air. He concludes that if such ulcers do not heal under the ordinary measures gastroenterostomy should be resorted to.

66 Gastric Carcinoma.—Zirkelbach has tested Salomon's method of diagnosis of cancer of the stomach in 10 cases of carcinoma and 37 of other diseases, and is convinced that it is reliable for the early diagnosis of cancer of the stomach. The method consists in washing out the stomach in the evening and then on the following morning introducing 400 cc of normal salt solution. This solution is removed after a short stay in the stomach and tested for the presence of albumin and for the proportion of nitrogen. Marked turbidity with Esbach's reagent (picric acid) or the presence of more than 30 mg of nitrogen indicates the presence of carcinoma.

67 Febrile Syphilitic Affections of Various Organs.—Raubitschek reviews 35 publications on this subject and emphasizes the necessity for wearing the possibility of a syphilitic affection in mind when confronted with a persistent hectic fever of dubious origin. Syphilitic affections of the liver, lungs and other organs may run their course with only slight or vague symptoms attracting attention to the organ. On the other hand, a febrile, acute tuberculous affection of the

lungs may lead to a fatal termination in a syphilitic without the lues being directly responsible for it. In some of the cases reported an exploratory incision revealed a gummatous affection of the liver or other organ, and all symptoms subsided under mercurial treatment. The syphilitic affection may simulate acute articular rheumatism. In Klemperer's case a man of 30 had suffered for months from fever with a slight chill every evening, followed by sweating. Long continued quinin treatment gave no relief, but mercurial injections had an astonishing effect. The liver and spleen returned to normal size, the fever vanished, and the patient has been in good health since.

68 Tuberculin in Diagnosis and Treatment.—About 350 articles are reviewed by Weiss without drawing any definite conclusions from the data presented by the various authors, although the important points are discussed in turn.

69 Old and New in Rachitis.—Zesas' article was commenced in No. 9 and is concluded in No. 18 of this publication. He cites Heubner, Bokai, Troitzky, Rauchfuss and others as advocates of phosphorus in treatment of rachitis, especially in combination with cod liver oil, the results obtained surpassing those recorded from any other means of treatment. Cod liver oil without phosphorus is sometimes given in small doses, a teaspoonful or two during the meals. Lime seems to be ineffectual, but when the child has started on the road to recovery, and the osteoid tissue has become capable of taking up the lime, then its administration seems rational. Stöltzner gives 0.5 gm calcium carbonate three times a day. Lime water contains too little lime, less than the same amount of cow's milk. Bernard has reported good results from administration of dog's milk. Iron preparations seem to do good service, especially in cases in which cod liver oil is not tolerated. Medicated baths have also been found useful, especially those with sea salt. Henoch has the legs rubbed with flannel during the bath and others have used massage with benefit. Good results have also been reported from galvanization along the spine and from electric baths. In extreme craniotabes the head of the child should be supported on a soft ring cushion. Fueth has used to advantage an apparatus to ensure respiration of condensed air to combat the rachitic deformity of the chest. This not only benefits the bony frame, but also helps to develop the lung tissue. Rachitic kyphosis should be combated by having the child lie on a hair mattress instead of being carried in the arms, or a plaster cast may be used for young children and a Phelps bed for older ones. Hoffa's experience has been that the children all recover in from two to three months if kept on a strict antirachitic diet, lying flat, with massage of the muscles of the back. The position in which the child lies is important also in prevention of scoliosis. He generally supports the spine in such cases with a corset. Rachitic deformity of the leg is liable to subside spontaneously in the course of three or four years in children under six. In treatment, an apparatus with elastic pressure on the convex side and permanent traction on the concave side will be found most useful. The application of the apparatus requires such care on the part of parents to prevent decubitus that, as a rule, Hoffa advises operative treatment, manual osteoclasia, for young children, with instrumental osteoclasia for older children. Macewen performed osteotomy ten times on one patient before the limb was brought to the desired shape.

70 Scoliosis Accompanying Sciatica.—Oberndörffer concludes from his study of the various publications that have appeared on sciotic scoliosis that the most probable explanation of the scoliosis is from the extension of the disease process to the lumbar nerves. This factor distinguishes sciotic scoliosis from that due to mechanical static stress. Some writers mention the scoliosis as occurring in 90 per cent of their cases of sciatia, while others have observed it in 10 per cent or less.

71 Literature on the Gall Bladder and Biliary Passages.—More than 1,000 articles or books in various languages were consulted by von Bardenheuer in preparing his monograph describing his 286 operations for gallstones. He here reviews the entire list, with brief summaries of the more important

points in turn as he cites the titles in full. The titles are arranged alphabetically in two groups, the first containing the articles on the anatomy and physiology of the gall bladder and genesis of gallstones, and the second the articles on the pathology of the gall bladder and biliary passages since 1897. The list includes a number of inaugural theses, and is an international summary.

72 Leukemia and Pseudoleukemia of the Skin—Isler analyzes 44 communications that have been published on the cutaneous manifestations of lymphatic leukemia or pseudo-leukemia. Most of the writers report their cases without decisive comment. The cutaneous manifestations may be diffuse, suggesting eczema, or they may appear as tumors large or small, generally affecting the face and causing subjectively little disturbance, but accompanying the changes in the blood. Similar manifestations may appear with violent itching, generally with the so-called pseudoleukemia. In other cases the cutaneous manifestations may be associated with or show a tendency to transformation into fungoid mycosis, sarcomatosis of the skin or pernicious lymphoderma of Kaposi's type.

73 Lumbar Puncture—Kaupe discusses the diagnostic and therapeutic importance of lumbar puncture from analysis of 487 articles on the application of this measure in the clinic. He states that the consensus of opinion has established the harmlessness of the measure if due precautions are taken. Too large amounts of the fluid should not be allowed to escape and it should never be aspirated, and the measures should never be applied to an outpatient. Transient by effects such as hemorrhage, transient lesions of the nerves, head ache, vertigo, vomiting, irregular pulse or pains in the limbs, have been reported by a few writers, and Remak urges restriction of the measure to certain indications. Exceptional caution is necessary on suspicion of a tumor in the brain or in the cerebellum, on account of danger of hemorrhage in the tumor tissue, of variations in the intracranial pressure and of the shutting off of the fluid in the ventricle from the rest of the cerebrospinal fluid. In one case of otogenic meningitis no bad effects were observed, but in another case these were noted. Lumbar puncture is generally harmless in tuberculous meningitis, but again it may hasten the fatal termination. In case of hydrocephalus it can do no harm unless the foramen of Magendie is occluded. For diagnostic purposes lumbar puncture may prove of paramount importance. Chemical tests for albumin may prove very instructive, apart from the knowledge gained in regard to the pressure of the cerebrospinal fluid. Its principal value, however, is for cytologic and bacteriologic investigation. As a rule, Kaupe says, polynucleosis is observed with acute and mononucleosis with chronic affections of the central nervous system, especially of the meninges. Lymphocytosis is often an early and important symptom of progressive paralysis and tabes, and confirms the probable syphilitic etiology of tabes. Bacteriologic examination of the cerebrospinal fluid is sometimes the only means of diagnosing epidemic cerebrospinal meningitis. From the therapeutic standpoint, lumbar puncture is able to relieve and to improve threatening symptoms, at least temporarily and in many cases has a direct life saving and curative action. A number of such instances of its beneficial influence were reported in the last epidemic of meningitis in Germany. Epidural injection probably acts mainly by suggestion, but may sometimes be useful in this line.

76 Treatment of Diabetic Phthisis—Thorspecken has had considerable experience with diabetics suffering from pulmonary affections, and has found that careful treatment gives excellent results. The diabetes should be treated with the same energy as without the pulmonary complications. In one case a tuberculous affection of the larynx healed as the patient, a man, was cured of the glycosuria. He has since been in comparative health for 16 years. In another case a bilateral tuberculous process in the upper lobes with much emaciation was so much improved under treatment of the diabetes that the patient, a physician, was able to resume his practice and has gained nearly 12 pounds in weight. In another case the tuberculous process was primary, and in a long latent stage when the onset of the diabetes made it flare up again. The course of this case shows how neglect of the diabetes in an active tuberculosis soon avenges itself, and it also shows the benefit on the tuberculous infection of effectual treatment of the diabetes.

80 Passive Hyperemia in Treatment of Seasickness—Roosen has derived much benefit in seasickness from Bier's method of inducing hyperemia in the head by an elastic band around the neck. His personal and clinical experience as ship physician showed that this measure was able to induce subjective well-being, but had no influence on the tendency to vomit when the stomach was full. When the stomach was empty, however, there was not the slightest tendency to nausea. The application of the elastic band must be individualized and must be supervised by the physician. It is not necessary to keep it up during the night, when the patients are reclining.

84 Laparotomy for Chronic Inflammation in Adnexa—Esch relates the experiences at Olshausen's clinic with 83 cases of chronic inflammatory affections of the adnexa treated by a laparotomy. The mortality was 7.2 per cent. The open abdominal cavity was protected with sponges against the bursting of a pus pocket, and every effort was made to leave the abdominal cavity as dry as possible before suturing the incision, without rinsing or draining. Olshausen says that any pus that can be seen during the operation can be readily wiped away and any that escapes observation must be in such small amounts that it could not be eliminated through a drain. If the infectious fluid has poured out in such quantities that it has worked its way between the loops of intestines, then nothing is to be gained by drainage. Rinsing out the cavity is liable to distribute the infectious material over a still larger surface, he thinks. He operates only in an interval period, and not until nine months after the date of infection, trusting that the bacteria have perished by this time. In three instances there was a communication between the pus pocket and the vagina, illustrating the complete failure of palliative treatment by mere incision in case of suppurative affections in the adnexa.

90 Implantation of Ureter in Bladder—Franz reports 15 cases in which the ureter was implanted in the bladder. His technique was worked out on the cadaver and on animals. He found it necessary to avoid crushing the ureter at any point and to use as little suture material as possible. He has performed the operation in 20 cases, but in five the patients succumbed to the effects of cancerous degeneration and they are not included in this report. In one of the other cases one ureter was severed in the course of an abdominal operation for removal of uterine cancer, and the ureter was implanted in the bladder, in another case the operation was for removal of a

cancer in the bladder, and in another of a myoma in the uterus. Twice both ureters had to be resected and implanted in cancer operations, and in three instances a fistula between the ureter and vagina was cured by implanting the ureter in the bladder. In another case the ureter was injured during a vaginal hysterectomy and had to be implanted in the bladder. The results, both immediate and remote, of the operations on the ureters were extremely beneficial in most cases and did no harm in any instance. In two other cases it proved impossible to implant the injured ureter in the bladder, and the kidney above had to be removed. The individual technic in each case is described in detail.

91 Pathogenesis and Treatment of Gastric Ulcer.—Marchetti calls attention to the fact that both the sympathetic and vagus are involved in the innervation of the stomach, and states that these two nerves are the ones that generally suffer most in nervous disturbances. He has made a number of experiments on animals which confirm his clinical experiences and suggest that lesions in the vagus—the motor nerve of the stomach—causing local paralysis, entail stagnation of stomach contents at the part involved, with ulceration in time. When the vagi are divided or ligated the motor function of the stomach is completely arrested and death is only a question of a few days. Ligating the right vagus paralyzes only the right half of the stomach, and in his experiments the center of the paralyzed part soon showed the typical ulcer while the rest of the stomach remained normal. The animals all vomited soon after eating, as do persons with an incipient ulcer. He attributes this to excitation of the vomiting center from the mechanical irritation of the food at the seat of the incipient ulceration. He thus explains ulcer of the stomach as the result of some change in the vagus interfering with the normal motor function of the part of the stomach innervated by the branch of the nerve in question. Particles of food collect at this point, which ceases to share in the general peristalsis of the organ, and stagnation is sooner or later followed by ulceration. He also states that treatment of ulcer of the stomach should aim to restore the injured vagus to normal, when the ulcer will heal of itself. If this can not be done, then the only course is to excise the paralyzed portion as the conditions that induced the development of the ulcer persist and the ulcer is liable to be reproduced at any moment. In his experimental research, ligation of one branch of the vagus, causing local paralysis of part of the stomach, was invariably followed in the course of about four weeks by the development of an ulcer, similar in every respect to simple, chronic gastric ulcer in man. Gastroenterostomy always cured the ulcer in his animals, and he advocates it for severe cases in man as the ideal procedure.

93 Passage of Mercury Through the Placenta.—Conti has been studying this subject both in the clinic and in experiments on animals, and his conclusions are that mercury administered to the mother does not pass through the placenta to the fetus. He believes, however, and his research seems to demonstrate the fact, that the mercury in the maternal organism causes the production of substances—antibodies—which are able to pass through the placenta to the fetus and to act on the specific agent of the disease, neutralizing its action.

95 Experimental Rabies in the Rat.—Mazzei relates experiences with rats inoculated with rabies which have convinced him that rats are much better adapted than dogs, monkeys or other animals for experimental study and control of the action of rabies virus and antibodies.

Books Received

Acknowledgment of all books received will be made in this column and this will be deemed by us a full equivalent to those sending them. A selection from these volumes will be made for review, as dictated by their merits, or in the interest of our readers.

ANESTHETICS AND THEIR ADMINISTRATION. A Text book for Medical and Dental Practitioners and Students. By Frederic W. Hewitt, M.V.O., M.A., M.D., Cantab., Anesthetist to His Majesty the King. Third Edition with Illustrations. Cloth. Pp 627. Price, \$4.00 net. London and New York: The Macmillan Co., 1907.

PEDIATRICS. The Hygienic and Medical Treatment of Children. By Thomas Morgan Rotch, M.D., Professor of Pediatrics, Harvard University. Fifth Edition. Rearranged and Rewritten. Illustrated. Cloth. Pp 1060. Price, \$6.00 per volume. Philadelphia and London: J. B. Lippincott Co., 1907.

HISTOLOGIC OBSERVATIONS ON SLEEPING SICKNESS AND OTHER TRYPANOSOME INFECTIONS. By F. W. Mott, M.D., F.R.S. (From the Pathologic Laboratory of the London County Asylums). Cloth. Pp 50. Price, \$1.50 net. New York: William Wood & Co., 1907.

AIDS TO DIAGNOSIS AND TREATMENT OF DISEASES OF CHILDREN. By John McCaw, M.D., R.U.L., L.R.C.P. Edin., Physician to the Belfast Hospital for Sick Children. Third Edition. Cloth. Pp 381. Price, \$1.25. New York: William Wood & Co., 1907.

TEXT BOOK OF MATERIA MEDICA FOR NURSES, Including Therapeutics and Toxicology. By G. P. Paul, M.D., Attending Physician to Samaritan Hospital, Troy, N. Y. Cloth. Pp 242. Price, \$1.50 net. Philadelphia: W. B. Saunders Co., 1907.

PSYCHOLOGY APPLIED TO MEDICINE. Introductory Studies by David W. Wells, M.D., Lecturer on Mental Physiology in Boston University Medical School. Cloth. Pp 141. Price, \$1.50 net. Philadelphia: F. A. Davis Company, 1907.

DERMATOLOGISCHE VORTRÄGE FÜR PRAKTIKER. Heft 7. Die ambulante Behandlung der Unterschenkelgeschwülste. By Dr. Jessner. Dritte Auflage. Paper. Pp 52. Price, Mk. 9. Würzburg: A. Stuber's Verlag (Curt Kabitzsch), 1907.

MANUAL OF DIAGNOSIS AND TREATMENT OF DISEASES OF THE EYE. By Edward Jackson, A.M., M.D., Professor of Ophthalmology in the University of Colorado. Cloth. Pp 616. Price, \$2.50 net. Philadelphia: W. B. Saunders Co., 1907.

THIS LABYRINTHINE LIFE. A Tale of the Arizona Desert. By George Alexander Fischer, author of Beethoven: A Character Study. Cloth. Pp 382. Price, \$1.20. New York: B. W. Dodge & Co. Chicago: A. C. McClurg & Co., 1907.

UNIVERSITY OF PENNSYLVANIA. The Provost's Report for the Year Ending Aug. 31, 1906. Seventh Series, No. 3. Part 6. Paper. Pp 298. Philadelphia: Published by the University, February, 1907.

AIDS TO DENTAL SURGERY. By A. S. Underwood, M.R.C.S., L.D.S., and D. Gabell, M.R.C.S., L.R.C.P., L.D.S. Second Edition. Cloth. Pp 128. Price, \$1.00. New York: William Wood & Co., 1907.

ANNUAL REPORT OF THE BUREAU OF HEALTH for the Philippine Islands. Victor G. Helser, Director of Health, July 1, 1905-June 30, 1906. Paper. Pp 160. Manila: Bureau of Printing, 1906.

AIDS TO MEDICAL DIAGNOSIS. By Arthur Whiting, M.D., M.R.C.P. Physician to the Tottenham Hospital. Cloth. Pp 152. Price, \$1.00 net. New York: William Wood & Co., 1907.

TWELFTH REPORT of the Board of Health of the Town of Montclair, New Jersey. From Jan. 1, 1906 to Dec. 31, 1906. Paper. Pp 70. New York: Jones Printing Co., 1906.

INTERNATIONAL MEDICAL ANNUAL. A Year Book of Treatment and Practitioners' Index. 1907. Twenty-fifth Year. Cloth. Pp 644. Price, \$3.00. New York: E. B. Treat & Co.

MECKEL'S DIVERTICULUM IN SURGICAL PRACTICE. (In Russian). Sixty-two Illustrations. By Prof. M. I. Rostovtzeff. Paper. Pp 154. St. Petersburg: V. C. Ettinger.

INTERNAL HYDROCEPHALUS

WITH REPORT OF TWO CASES, ONE RESULTING FROM OCCLUSION OF THE AQUEDUCT OF SYLVIVS *

WILLIAM G SPILLER, M.D

Professor of Neuropathology and Associate Professor of Neurology
in the University of Pennsylvania.

AND

ALFRED REGINALD ALLEN, M.D

Assistant in Neuropathology in the University of Pennsylvania.
PHILADELPHIA.

It is by no means rare to find occlusion of the aqueduct of Sylvius as one of the etiologic factors in internal hydrocephalus mentioned in text-books dealing with this subject. Attention is particularly attracted by the fact, however, that no references are given in most of the articles which refer to this occlusion as a possible cause, whereby one can determine that the author is speaking from clinical experience and not theorizing.

We have been struck with the *a posteriori* nature of discussions on this subject, and it is therefore with pleasure that we bring forward a case of internal hydrocephalus the cause of which is probably congenital almost total occlusion of the aqueduct of Sylvius.

Anton,¹ in dealing with the causes of hydrocephalus, quotes Baginsky's opinion that acute hydrocephalus is identical with acute non-tuberculous inflammation of the choroid plexus and the following increase of exudation. He adds that there is without doubt involvement of the ventricle walls and the ependyma. He also advances the view held by Rindfleisch, Huguenin and Von Bonninghaus to the effect that the inflammatory affection of the ventricles and choroid plexus is always associated with a meningitis serosa or purulenta, and that these are caused by toxic or infectious factors. Referring to Macpherson, he states as a possible cause an infectious phlebitis with thrombus formation of the venous sinuses. He says that occasionally the exciting agent of the inflammation gains access directly to the ventricle through the brain substance, with or without traumatism, and there sets up a fibrino-purulent process. Lastly he calls attention to a possible connection between rachitis and hydrocephalus.

Gowers² holds that the "only known cause" of acute hydrocephalus is meningitis. Speaking of chronic internal hydrocephalus he makes this interesting statement: "Sometimes all the ventricles are distended, more often the fourth ventricle suffers little even where there is no obstruction in the aqueduct of Sylvius. In such a case the aqueduct may be funnel-shaped, dilated

towards the enlarged third ventricle." This statement should be compared with the gross anatomical findings of our second case. Gowers further mentions the possible obstruction of the veins of Galen preventing the return of venous blood from the intraventricular vessels and thereby becoming a cause. Such a condition as this, if acute, is likely to cause ventricular hemorrhage and rapid death, as in a case reported by one of us (Spiller) with Wadsworth, but when developing slowly might be productive of internal hydrocephalus.

Oppenheim³ speaks of compression of the aqueduct of Sylvius as a cause of internal hydrocephalus. D'Astros⁴ states that an obstruction of the aqueduct of Sylvius will produce *une hydropsie* of the third and lateral ventricles, but he gives no instance of its so doing. A Henle⁵ says that a closure of the aqueduct of Sylvius will cause a hydrocephalus confined to the third and lateral ventricles, but he gives no reference to a case. P Bournville⁶ speaks of "another case" of hydrocephalus caused by the obliteration of the aqueduct, but no further information is given. F Schultze⁷ mentions the possibility of hydrocephalus being caused by the obstruction of the aqueduct, and refers to Seeligmuller's cysticercus case which we cite below.

Seeligmuller⁸ speaks of a possible pressure on the aqueduct of Sylvius by a tumor causing hydrocephalus. In the same work he gives the history of his case of hydrocephalus caused by the plugging of the aqueduct by a cysticercus the size of a cherry stone. Apropos of cysticercus Karl Osterwald⁹ has collected about thirty-four cases in literature of cysticercus in the ventricles of the brain, but in none of the cases given was the parasite in the aqueduct.

Bonninghaus¹⁰ gives as a cause of hydrocephalus, what he terms an "acute automatic closure" of the aqueduct of Sylvius. By this he means that when the effusion into the third and lateral ventricles occurs rapidly, the more yielding portions of the third ventricle, i. e., the floor and the roof, become displaced and pull from above and below on the more solid pons and in this way produce an elongation of the aqueduct which may result in complete closure.

One of us¹¹ (Spiller) reported a case in which the third and lateral ventricles were dilated and the aqueduct was occluded by proliferation of the neuroglia. Two other cases of partial internal hydrocephalus have come under his notice. In one the distension was confined to one lateral ventricle of the brain and was caused by partial

inflammatory closure of the foramen of Monro, in the other case only the posterior horn of the lateral ventricle was distended, and very greatly, from unknown cause. In this case the occipital lobe of the affected side was a mere sac. He also refers to a case of Bourneville and Noir,¹² in which the aqueduct was entirely occluded, but there was no microscopic study of the tissues. In this same paper he (Spiller) speaks of Touche's case,¹³ in which there was occlusion of the aqueduct.

Our first case was reported by one of us (Spiller) without microscopic study.¹⁴ The history as obtained from the Pennsylvania Training School for Feeble-minded Children is as follows:

Patient—Sally H., age 62 at time of death, American.

History—Father died of consumption, aged 39, mother died aged 63, cause unknown, two brothers and two sisters died of consumption. One sister (the first born) died in early infancy, cause unknown, two brothers are living in good physical and mental condition. Of the details of the patient's birth nothing is known. She was supposed to have been born hydrocephalic and was weak and sickly as a baby. Sight, hearing and speech were good. She had epilepsy for years and during her seizures would froth at the mouth and purge. She suffered frequently from vomiting without assignable cause, and had occasional attacks of vertigo. She was said to have chronic kidney disease six years prior to her death. There was no paralysis at any time, and although no joint complication was present she always walked as though lame. She was said by Dr. Llewellyn, who had known her for years, to have been fairly well developed mentally. Her advanced age and her mental condition are remarkable in view of the extensive hydrocephalus.

Macroscopic Examination—The third and lateral ventricles of the brain were greatly dilated and the white matter surrounding them was intensely atrophied. The whole cerebrum appeared as a greatly distended sac. The lateral ventricles freely communicated with one another, and the walls of the third ventricle were so pushed apart that the floor of this ventricle was on a level with the upper part of the basal ganglia.

Microscopic Examination—Left Optic Thalamus. The blood vessels were thickened and there were some recent hemorrhages within the substance of the thalamus. All the vessels were distinctly congested. There was little vacuolation of the cells of the choroid plexus such as described by Raubitschek.¹⁵

Corpus Callosum. A section from the median portion of this structure was not more than 1 mm. in thickness, it stained normally and contained numerous amyloid bodies.

Left Occipital Lobe. In places the cortex and white matter were not more than 2 mm. in thickness, in other places the thickness was 6 mm. The atrophy was relatively much greater in the white substance than in the cortex. Where the width of the section was the least, more than half was occupied by the cortex. The cells were much diminished in number as shown by the thionin method.

The Fornix. This was much atrophied and the blood vessels within it were greatly thickened.

The aqueduct was almost occluded, this occlusion being probably a congenital malformation because the cavity was well lined throughout by a layer of ependymal cells, which would hardly be the case if the occlusion were caused by proliferation of the neuroglia. The neuroglia tissue immediately adjoining the ependymal lining was a little proliferated, and the aqueduct was filled with red blood corpuscles which were unaltered in shape, and probably were deposited there shortly before death. To the naked eye the aqueduct seemed to be entirely occluded. In a microscopic section the aqueduct to the naked eye was hardly as large as the point of an ordinary pin.

The second case is reported as one of intense congenital hydrocephalus without occlusion of the aqueduct.

The pathologic material was received from Dr. Thompson S. Westcott, to whom the case belongs. The patient lived to be a year and a half old. The skull was excessively large. It is difficult to describe the gross appearance of the brain other than to say that it was a large thin bag of nerve tissue so attenuated in many places as to be translucent, and the mere handling of it caused numerous tears in its substance.

Microscopic Examination—The corpus callosum was not more than 0.5 mm. thick.

Left Occipital Lobe. Sections in places were not more than 1 mm. thick. Here, as in the other case, the atrophy was much more pronounced in the white matter than in the cortex.

Left Motor Area, Median Side. The white matter was most affected. There was great diminution in the number of cells and the pericellular spaces were all distended. The cells appeared all decidedly smaller than normal. The pia was not thickened and the cortex and white matter were 4 mm. thick.

In contrast to the other case the fourth ventricle was greatly dilated as the result of the dilatation of the aqueduct of Sylvius. The cause of the hydrocephalus in this case could not be determined, but the condition seemed to have been a congenital malformation.

The two cases show very clearly that the distension of the fourth ventricle may depend on the patency of the aqueduct of Sylvius.

MYXEDEMA A STUDY *

CAMPBELL P. HOWARD, M.D.

Outdoor Physician to the Montreal General Hospital
MONTREAL, CANADA.

INTRODUCTION

HISTORICAL NOTE

In 1873, in a paper entitled "A Cretinoid State Super-vening in Adult Life in Women," Sir William Gull¹ first described the disease known later as myxedema. This name was suggested by Ord,² in 1877, as he said, "To be applied to an essential condition in the cretinoid affection occasionally observed in middle-aged women." He also wrote:

The whole collection of symptoms are related as effects to jelly like swellings of the connective tissue, chiefly, if not entirely, consisting in an overgrowth of the mucous yielding cement by which the fibrils of the white element are held together. Accordingly, I propose to give the name of "myxedema" to the affection.

He further emphasized the similarity of myxedema and cretinism and among other things pointed out that in one of his cases (as in one of the cretins reported by Curling), there was diminution in size and almost complete annihilation of the thyroid gland. Charcot³ in 1880 proposed the name "cachexie pachydermique." He writes:

L'expression pachydermique nous paraît bien rendre compte des traits dominants du tableau clinique et qu'elle en donne une idée sinon plus exacte, tout au moins plus vivante que la dénomination des auteurs anglais.

J. L. Reverdin⁴ in a paper before the Medical Society of Geneva in 1882, called attention to a train of symptoms following the total extirpation of goitrous thyroid glands. The symptoms which he enumerated were

weakness, languor, hebetude, pallor and edema of the face and hands, without albuminuria. One case he states "was very analogous to a cretin." A year later (1883) the same author⁵ pointed out the similarity of the group of symptoms to the myxedema of the English writers and named the condition "myxedema postopérative." He rightly attributed it to a loss of the thyroid gland. At the twelfth congress of the German Surgical Association in 1883, Kocher⁶ described a similar train of symptoms following total thyroidectomy to which he gave the name, "cachexia strumpriva." He, however, thought the condition was due to a mechanical injury to the structures of the neck, resulting in a chronic asphyxia. Later Kocher acknowledged his mistake and accepted the view of Reverdin and Semon.

Sir Felix Semon,⁷ of London, next pointed out the correlation of myxedema and cachexia strumpriva and suggested a common causative factor, namely, a loss of function of the thyroid gland. Paul Bruns, in 1884, reported the case of a boy, aged 10, in whom extirpation of the thyroid gland was followed by the condition known as sporadic cretinism.

These observations led the Clinical Society of London to appoint on Dec. 14, 1883, a special committee to investigate this subject. The members of this committee immediately set about their researches and in 1888 published their monumental report⁸ which has formed the groundwork for all later investigation of the subject. The committee comprised such men as Victor Horsley, who directed the experimental work, William Ord, who collected the clinical data, and Halliburton who investigated the chemistry of the tissues. In 1887, Virchow contributed some data to our knowledge of the pathology of the disease. More recently many valuable contributions have been published, which will be discussed later.

In America the first case of myxedema was reported in 1881 by W. A. Hammond.⁹ In 1888 Hun and Prudden¹⁰ described in detail 4 cases of their own and reviewed the literature up to the date of publication.

DEFINITION

In his monograph, Murray¹¹ defines myxedema as follows:

It is an affection characterized by widespread changes in nutrition as shown by the appearance of solid edematous swelling of the subcutaneous tissues, dryness of the skin and arrest of development of its appendages, subnormal temperature, slowness in the mental processes and in the execution of voluntary movements.

CLINICAL VARIETIES

Under the general term myxedema are included three groups of cases: 1, cretinism; 2, myxedema proper; 3, operative myxedema.

1. Cretinism.—This is a chronic affection, either congenital or appearing at any time before puberty. Osler¹² says:

It is characterized by disturbance of the growth of the skeleton and soft parts, a remarkable retardation of development, an extraordinary disproportion between the different parts of the body, and a retention of the infantile state with a corresponding lack of mental progress.

Three sub-varieties of cretinism are now recognized:

a. Endemic cretinism which develops in certain localities of Italy, France and Switzerland, in association

with goiter under local conditions of an obscure toxic nature. No cases of this variety have occurred in America.

b. Sporadic cretinism in which the thyroid gland may be congenitally absent or atrophied after one of the specific fevers or in association with goiter. In 1897 Osler¹³ collected 60 cases of this type in America. Many more cases have since been reported.

c. Juvenile myxedema is a term suggested by Parker for a small group of cases occurring in children who have developed physically and mentally until their fourth or fifth year at least, at which time the symptoms occur in consequence of atrophy of the thyroid gland following in all probability an acute thyroiditis in the course of an infectious fever, as typhoid, scarlatina, etc. In this group there are the usual symptoms of the adult form, but there is also an arrest of development at that stage of a child's growth when the disease set in. Osler and others in America have reported a few instances of this variety.

Pineless¹⁴ in a very excellent paper has recently drawn sharp lines of demarcation between three types of cretinism, which are practically identical with the foregoing. His varieties are a, Thyroaplasie or congenital myxedema; b, infantile myxedema; c, endemic cretinism. The first type, though rare, includes some of the sporadic cases. The second comprises those cases in which atrophy of the gland occurs in association with goiter or follows one of the specific fevers, the third is identical with endemic cretinism above described.

A remarkably elaborate monograph on "Cretinism" by Wilhelm Scholz,¹⁵ of Graz, has recently appeared, and is well worth a careful perusal. His clinical material is particularly rich, and some of his conclusions are both interesting and original.

2. *Myxedema Proper*.—This includes those cases in which the symptoms develop in an adult at any age after puberty.

3. *Operative Myxedema or Cachexia Strumpriva*.—This is the variety in which the symptoms of myxedema develop after a total thyroidectomy for goiter or other disease of the thyroid gland. Of this variety there are two different types, the cretinous and the adult myxedematous, according to the age of the patient at which the gland was removed.

In the American literature prior to July 1, 1905, I find but two cases of operative myxedema. The first, Dr. McGraw's case, which is briefly referred to by Osler,¹² occurred in a young man in whom a complete thyroidectomy for goiter at the age of 12 was followed six years later by the gradual development of the typical myxedematous features which persisted for 12 years. A second case was mentioned by Huntington¹⁶ at a meeting of the California Academy of Medicine, Nov. 27, 1900. This patient was also a male in whom myxedema followed one year after complete thyroidectomy. More recently Moffit¹⁷ states that two cases of postoperative myxedema have occurred in California, one of which was in all probability Huntington's case. I have not included any of these cases in my series which is restricted to myxedema proper.

Abortive forms occur in myxedema just as in exophthalmic goiter. The French have suggested the term

"myxedemie fuste" J L Reverdin¹⁸ in 1886 first noted this form in cases following partial thyroidectomy in which there was subsequent atrophy of the remainder of the gland. In these cases there may be no mucinoid infiltration of the skin but there is a liability to swelling and localized hypertrophy of the mucous membranes of the nose, throat, etc., as well as a predisposition to tonsillar enlargement and adenoid formation. Further, the teeth may decay early and the hair fall out prematurely. The French consider loss of the outer half of the eyebrow as almost pathognomonic of this type of the disease. In women there is also a tendency to circulatory disturbances of the mucous membranes at the menstrual period or a hyper-sensitiveness of the nose, throat or even of the vaginal mucous membrane. Chronic constipation, painful joints, vague pains between the shoulders, paresthesiæ and an occasional giving way of the legs, are other obscure manifestations of the disease. Moffitt¹⁷ has reported 11 cases of this type, in all of which definite improvement followed thyroid medication.

CASE REPORTS

The following 10 cases occurred in the practice of Dr William Osler, either in private or in the wards of the Johns Hopkins Hospital.

CASE 1—White female, aged 37, multipara, sister of patient in Case 2, a second sister with exophthalmic goiter, a third sister with Raynaud's disease, three years' duration, thyroid therapy, loss of 54 pounds, recovery (Previously reported by A R Oppenheimer)

Patient—M. D., American, housewife, of Virginia, was admitted Jan. 28, 1894, to the Johns Hopkins Hospital complaining of "swelling of the body."

History—The parents were not blood relatives, of two brothers one had "renal trouble." There were three sisters, one of whom is the patient in Case 2 of this series, another had exophthalmic goiter and died from "peritonitis," and a third later consulted Dr Thayer (October, 1905) for Raynaud's disease. Patient had always been healthy and had borne five children.

Present Illness—This dated back three years (1891), when at the age of 34, while pregnant, she underwent a prolonged physical and mental strain. Subsequently she gave birth to a child, which lived only three months. About three months after delivery and about ten days before her menstrual period, she first noticed that her entire body became more or less swollen, but did not put on pressure. This swelling was repeated before subsequent "periods," but would disappear temporarily with the onset of the flow. A year before admission (1893) the menses became less frequent, being at intervals of from six to eight weeks. The swelling also became more or less constant, though it was more pronounced at certain times. The tongue began to feel stiff and swollen. Later the skin became dry, harsh and rough, there was some loss of hair and a constant chilly sensation. The bowels were constipated. The appetite was good. Micturition was free, but never excessive. There was no loss of memory or difficulty of speech.

Physical Examination—On Feb 26, 1894, examination revealed a very large woman of medium height, weighing 189 pounds. She was very garrulous. The face was heavy, rather dull and expressionless. The cheeks and neck were very full and with an almost edematous appearance. The complexion was doughy, without any marked hectic flush. The supraclavicular regions were moderately full. The arms and legs were decidedly swollen. The dorsal surfaces of the hands and feet were very puffy and edematous looking, but nowhere pitted on pressure. The skin had a resistant feel very dry and in some places showed a little scaling. The hair was rather dry and coarse. The finger nails were thin, with marked longitudinal striations, and a slightly everted and very irreg-

ular free edge. The thyroid gland could not be felt, though, owing to the thickness of the neck, it was impossible to determine any diminution in its size.

The abdominal and thoracic viscera were normal. The pulse ranged between 60 and 68 to the minute. The temperature in the mouth ranged between 97.6 and 98.4 degrees. The urine had a specific gravity of 1020, and on two examinations contained neither albumin nor casts.

Clinical History—Jan. 27, 1894. Five grains of desiccated sheep thyroid were given three times a day.

January 31. In the evening there was a very striking fullness over both clavicles, and a mass the size of a hen's egg was present in each fossa. These disappeared by next morning.

February 2. For the first time she complained of weakness, headache and pain in the back. The pulse had become more rapid, ranging from 80 to 90 to the minute. There was sweating and some nausea. She had taken but 65 grains in the five days, and had lost 8 pounds. The dose was reduced to 5 grains twice a day.

February 9. She had then taken 160 grains of thyroid. The temperature and pulse range since February 2 was 98.4 to 99.5 degrees and 84 to 108, respectively. There was a loss of 10½ pounds during twelve days' treatment.

She was discharged from the hospital much improved, with directions to continue the treatment at home.

Further History—A letter from her physician, Dr H B Melvin, stated that her improvement continued. During the first twenty five days of treatment she had lost 25 pounds, and the loss continued until she then was very nearly her normal weight.

November, 1894. She was then taking only 3 grains every second day, and though eight months' pregnant, was very well.

Sept. 30, 1896. The patient was readmitted to the hospital for observation. "Her condition beyond being nervous was very good." The skin was soft and natural and there was no edema.

October 1. Her weight was 135 pounds, i. e., a loss of 54 pounds since admission in 1894.

October 9. After a few days' rest in the hospital she was discharged.

Oct. 21, 1905. The patient consulted Dr Thayer, who kindly gave me the following notes: "She has regarded herself as well since leaving the hospital. She has, however, taken the thyroid intermittently. Her ordinary course has been to take 5 grains of Armour's extract in capsules three times a day for four or five days, then to stop taking anything for two or three weeks at the end of which time she begins 'to feel slow and tired and to swell.' This swelling consists of a puffiness of her hands and shoulders. The ankles are continually puffy. Her pulse is always slow and she is always rather susceptible to cold, a susceptibility which is much more marked after she has stopped taking the thyroid for a considerable length of time."

On examination, "she looked well and bright. The face, however, was a little heavy and above the clavicles there was rather a marked fullness. The hands were chubby, but nothing more. About both ankles there was a marked elastic puffiness. Between the sternomastoids in the region of the thyroid there was a distinct hollow, the thyroid was not to be felt. The pulse was 68."

CASE 2—White, female, aged 19, nullipara, sister of patient in Case 1, exophthalmic goiter (previously reported by A R Oppenheimer), readmitted at 22 with myxedema, no trace of goiter, thyroid therapy, recovery

Patient—S E., American of Virginia, was admitted Jan 26, 1894, to the Johns Hopkins Hospital, complaining of "enlargement of thyroid gland" and "great nervousness."

History—Her family history was the same as that of her sister the patient in Case 1. Patient had measles and scarletina in childhood. Menses had always been irregular appearing only once in the previous year. Patient was single and had borne no children.

Present Illness—This began in 1891, three years before admission, when after a severe fright she became very nervous, excitable and restless. There were frequent palpitations of the heart. The thyroid gland became enlarged in 1893 and re-

maintained so. There were attacks of dyspnea due, the patient thought, to pressure on the trachea by the goiter. There was also tremor of the hands following any excitement. The voice became husky, the eyes became a little more prominent. The appetite was good, there was no nausea and no vomiting. Bowels were regular, there was no cough.

Physical Examination—Examination on Sept. 20, 1894, revealed a slight though well nourished girl, of very neurotic temperament. The face was flushed and there were numerous areas of transient flushing of the skin over the body. There was a decided double exophthalmos, but von Graefe's sign was absent. There was marked symmetrical enlargement of the thyroid gland. The apex beat of the heart was in the sixth interspace, the impulse was powerful and heaving, first sound markedly booming. The lungs and abdominal viscera were negative. The urinalysis showed a specific gravity of 1012, with a slight trace of albumin, but no casts. The pulse was rapid from 110 to 120 to the minute. Temperature was 99 to 99.5 degrees. Weight was 137 pounds.

Clinical History—January 27. A diagnosis of exophthalmic goiter was made and the patient was given thyroid extract gr. v, t.i.d.

February 2. A very definite fine tremor of the hands was noted.

February 9. She was discharged after having taken 200 grains of thyroid extract and having lost 2½ pounds (134½ pounds).

Subsequent History—November 22. After her discharge from the hospital she was given tincture belladonnæ, gr. xv, t.i.d., for two months, which resulted in some diminution in the size of the goiter and in the degree of exophthalmos.

May 7, 1897. Patient was readmitted. She was then aged 22 and single. She complained of "general swelling" and "soreness."

After leaving the hospital in 1894 she had not felt very strong and was unable to take any active exercise. In January, 1896, her friends noticed that she was becoming stout, and the patient found that her collar was getting tight and that her shoes would not button. The swelling was general, including the supraclavicular regions. It was more pronounced after exercise and in the afternoon. She felt very drowsy and "not up to anything." Her speech became slow. Occasionally the skin of the hands and face around the mouth would turn purple. She suffered from the cold, especially in the evenings, and she became very nervous. Bowels were regular. There was no increase in the amount of urine. She was given thyroid extract three times a day by her physician, and at first improved, but later became so weak that she was unable to sit up and the dose was reduced.

Second Physical Examination—Examination on May 7, 1897, revealed a paler and little fuller faces than on previous admission. There was no puffiness above the clavicles. The goiter had entirely disappeared. The tongue was rather large, drvish and indented. The hands were a little full. The feet and legs above the ankle joints were swollen, but did not pit. The skin was harsh. Over the face was a marked vasomotor disturbance. There was marked dermatographia. Superficial reflexes were active. Except for a palpable right kidney the examination was negative.

Urine had a specific gravity of 1010, and contained neither albumin nor casts. The amount in twenty-four hours was 340 to 800 cc. Temperature was from 99.4 to 98.2 degrees, pulse, 60 to 98. Weight, 122 pounds (i. e., 12½ pounds less than on discharge, February 1894).

Further Clinical History—May 12, 1897. She was given thyroid extract, gr. ii, t.i.d., which, on May 23, was increased to gr. iv.

May 31. Dr. Osler noted that "the joints of the feet were painful, but not swollen or infiltrated. There was some puffiness of the wrist and face. The legs were much smaller and more natural. There was slight tremor. There was no enlargement of the thyroid gland, but the lobes could be felt. There was instability of the vasomotors of the skin, and a patchy chlorasma over forehead, chin and neck." Patient was discharged "much improved," having taken 186 grains of thyroid extract and having lost 4 pounds in weight (118 pounds).

Her temperature after beginning treatment was practically unaffected, being still always above normal, but the pulse ranged a little higher (70 to 112). The quantity of urine also showed some increase sometimes reaching to 800 and once to 950 c.c. in the twenty-four hours.

Oct. 21, 1905. Dr. Thayer learned from the sister (Case 1) that the patient "has grown rather worse. From time to time she has had definite mental symptoms, being 'flighty.' She feels that she is sick and that her presence in the house makes others sick and she tries at times to get away." At other times she is perfectly well except for "nervousness." There was no statement as to the use of the thyroid tablets.

CASE 3—White, female, aged 23, nullipara, consanguinity of grandparents and parents, duration four months, marked delusions and hallucinations, thyroid therapy, loss of 3½ pounds in two weeks, recovery.

Patient—E. T., German, tobacco factory girl of Baltimore, was admitted to the Johns Hopkins Hospital June 26, 1894.

History—Her paternal grandparents were first cousins. Her father and mother were healthy, but were second cousins. There was a history of tuberculosis in mother's family. There was no history of goiter, myxedema or neurosis in the family. Patient was born in Germany, in the district of Westphalia, but came to America at 16. She did not remember having seen any cases of goiter, etc., in her native village. Except for the diseases of childhood she had always been well and strong. The menses began at her fifteenth year and were regular until after her arrival in America when she had amenorrhea for three months. They returned and were regular until May, 1891. She came to the Johns Hopkins Hospital Dispensary on June 6, 1891, complaining of pallor, constipation, fulness after eating and loss of weight. Physical examination was practically negative except for slight chlorosis.

She occasionally attended the dispensary during the following year. The general condition improved markedly, though the catamenia did not return. Between April 9, 1892, and June 25, 1894, the patient was lost sight of. When last seen she was a rather delicately formed, well-nourished girl with good color and delicate attractive features. On June 26, 1894, she applied to the hospital for treatment and was admitted. The following additional facts were obtained. On July 15, 1893, she went to the country as chambermaid. While there her general condition improved greatly. The catamenia reappeared for the first time since 1891 and became regular, lasting three days without pain. She returned from the country Oct. 1, 1893, and went to work in a tobacco factory.

Present Illness—In February or March, 1894, her health began to fail. In April 1894, her family began to notice that her eyes appeared swollen. She herself observed loss of appetite, dryness of the throat and also a general dryness of the skin, with absence of sweating. The swelling increased and appeared also in the hands and arms. Her friends noticed that her voice became changed, being deeper and harsher, while she spoke in a distinctly slower, more expressionless manner. There was an unnatural thirst. She became very susceptible to cold and wore heavier clothes than formerly. She was very irritable and nervous and her ordinarily placid disposition entirely changed. Her sleep, however, was always good. In fact there was a certain tendency to drowsiness and she was easily fatigued. The bowels were constipated. There was no cough, but she complained of a heavy feeling in her chest. Several weeks before entry she began to have delusions. She feared that certain members of her family were going to poison her. She also believed that she was pregnant and insisted that she felt something moving in her abdomen. She declined to stay at home and went to the house of a companion who brought her to the hospital. She had gained slightly in weight.

Physical Examination—Examination by Dr. Thayer, June 26, 1894, revealed a most extraordinary change in her general appearance. There was marked puffiness, edematous condition of the face, hands and arms, which did not, however, pit on pressure. She had a peculiar muddy complexion. The puffiness was particularly marked about the eyes, the bridge of the nose and chin. There was a fulness over the clavicles but no marked edema. The hands and arms showed the same puffy appearance, without any pitting. She had an

dull manner, talked slowly, appeared suspicious and was distinctly irritable. She was reticent about stating her delusions and was unwilling at first to allow a physical examination. The urine was free from albumin. The thyroid gland could not be distinctly felt. A diagnosis of myxedema was made, and she was admitted to the hospital for observation. During the first four days there was little change.

Clinical History—June 30, 1894 Dr Thayer noted that the skin, particularly that of face and hands, was rather dry, harsh and resistant. The lips seemed thick. The general expression was dull and heavy, very similar to that in acute nephritis. The cheeks were pink in rather sharp contradistinction to the white areas elsewhere. The hair was dry, but the nails were well formed. The pulse was slow, 50 to the minute, regular and full. The thyroid gland appeared extremely small, being scarcely distinguishable on palpation. The heart, lungs and abdominal viscera seemed normal. The deep reflexes were not increased. There was no edema of the legs. She was placed on desiccated thyroid, gr m tid.

July 1, 2 and 3 The urine showed no albumin and no casts and a normal specific gravity (1020 to 1022).

July 4 There was a trace of albumin, but no casts.

July 5 Blood examination revealed Hb = 59 per cent, red blood corpuscles, 3,532,000, white blood corpuscles, 6,000. A differential count of 500 leucocytes gave

Polymorphonuclear neutrophils	Per cent
Small mononuclears	77.4
Large mononuclears	17.1
Eosinophiles	4.2
	1.3

There was no polikilocytosis.

July 9 The condition had changed materially since beginning the thyroid treatment 9 days before. The puffiness about the face had diminished, but scarcely as much as that about the hands and arms which had disappeared in a most remarkable manner. The mental condition had entirely cleared up and she was then bright and cheerful. Pulse was 104.

July 14 A further change in her condition was noted. While the face was still a little full, the edematous appearance about the eyes was almost entirely gone. The change in the hands and arms was almost more remarkable. The skin was no longer dry, but moist and warm, and she stated that there was a good deal of sweating. She was placid and cheerful. The blood count revealed Hb 69 per cent., red blood corpuscles, 6,124,000, white blood corpuscles, 8,500.

She was discharged on the fourteenth day much improved, having taken 270 grains of thyroid extract and having lost 3½ pounds.

The temperature, which was usually normal or slightly above, showed later a tendency to be subnormal. The pulse which formerly ranged between 72 and 86 became more rapid with the thyroid treatment and varied from 80 to 105. She was directed to continue the thyroid extract, but to increase the dose to gr vii tid.

Subsequent History—July 28, 1894 She returned to report herself as feeling perfectly well. The change in her physical condition was most extraordinary. All signs of puffiness were gone, her color was natural, her voice and manner as they used to be.

Sept 4, 1894 She again reported, she had gained materially in weight, and looked stronger and better. There was no sign of puffiness in the face or hands. She was then taking the glycerin extract, instead of the desiccated powder, every other day.

Dec 14, 1894 She was not feeling as well, as she had been more irregular in the use of the thyroid extract. The face was a little swollen and the skin dry. There was a tenseness about the skin of both hands and feet, but no swelling of the legs.

At intervals during the subsequent ten years Dr Thayer saw the patient who remained free from symptoms as soon as she recognized the absolute necessity of taking small doses of the thyroid gland.

Oct 20, 1905 The patient reported again at Dr Thayer's request. She stated that she still took a 5 grain tablet every day. If she omitted it for more than forty-eight hours she felt the bad effects. The general health was excellent. Men-

struation was regular. On examination she looked well. There was still a little roundness about the face and a peculiar expression about the eyes due to a little fullness of the lids, but so slight as to be overlooked by the casual observer. Her skin felt natural. There was, however, a striking depression over the thyroid cartilage and no trace of the gland could be felt.

(To be continued)

PATHOLOGY OF PARALYSIS AGITANS *

CARL D CAMP, M D

Instructor in Neuropathology and Electro-therapeutics at the University of Pennsylvania. Assistant Neurologist to the Philadelphia General Hospital.
PHILADELPHIA

The subject of the pathology of paralysis agitans is one on which few physicians have definite ideas, and those who have differ widely from each other. It is obvious that so long as the nature of this disease is in controversy and obscurity the treatment must be imperfect, changeable and unfortunately inefficient. Numerous investigations with the idea of clearing up this problem have but added to its complexity by suggesting new hypotheses and unexplored fields for research.

The clinical picture of paralysis agitans is so clear cut and typical, the course of the disease so unchangeable and progressive that it certainly suggests an organic basis. To classify it as a neurosis is begging the question and explains nothing, while it would be distinctly harmful if it hindered further search for the real pathology.

SUMMARY OF LITERATURE

In order to define the present status of our knowledge of the subject, it will be necessary to review briefly the findings and opinions recorded by numerous observers since Parkinson wrote his classical paper in 1817. For the sake of convenience these findings may be classified according to their location into: 1 Those in the nervous system, the brain, spinal cord and peripheral nerves; 2 Those in the muscles; 3 Those in the ductless glands.

The gross lesions in the central nervous system found by some of the earlier writers which were regarded by them as the cause of paralysis agitans are not now credited with such a relationship. It must be remembered that at that time the difference between multiple sclerosis and paralysis agitans was not well understood, consequently, in the opinion of Wollenberg,¹ one of the cases which Parkinson himself described was probably a case of multiple sclerosis and, according to the same authority, similar cases have been reported by Oppenholzer,² Marshall-Hall,³ Skoda,⁴ Lebert⁵ and others.

Confusion has arisen, also, from the fact that cases are reported in which paralysis agitans was combined

* From the Department of Neurology and the Laboratory of Neuropathology of the University of Pennsylvania.

* Read in the Section on Nervous and Mental Diseases of the American Medical Association at the Fifty seventh Annual Session June 1906. This paper was accompanied with a detailed report of fourteen cases for which TIME JOURNAL could not give space. The author offers to send a reprint of the complete article including the case reports, to anyone who requests it and sends a two-cent stamp for postage. The entire article will also appear in the volume of Transactions of the Section on Nervous and Mental Diseases of the American Medical Association 1906 and in the volume of Contributions of the Laboratory of Neuropathology of the University of Pennsylvania, 1907.

with multiple sclerosis as in the case reported by Furstner⁶ (his second case) and the case of Schultz,⁷ in which the diagnosis is questionable, as he only found areas of sclerosis of pinhead size ("Stecknadelkopfgrosse"), but Sanders⁸ thinks it should be included in this category. Many of the earlier writers recorded as paralysis agitans cases in which the tremor was symptomatic of some gross lesion of the brain, such as the case reported by v Leyden⁹ of a sarcoma of the left optic thalamus, also those of Charcot,¹ Benedikt,¹ and Blocq and Marinesco,¹⁰ who described cases of tremor caused by tumors situated in the region of the cerebral peduncles. Chvostek¹¹ reported a case in which clinically there was first paresis, then tremor of the extremities on the left side, and in which anatomically there was a sclerosis of the entire right cornu ammonis. Ordenstein¹² found in one case areas of softening in the cerebral peduncles, but in the two other cases reported by him at the same time the findings were negative. Herterich¹³ described a case with very marked contractures in which he found an area of softening in the left cerebral peduncle. Cases have been reported by Virchow,¹⁴ Leubuscher,⁸ Berger⁷ and others in which areas of softening in the brain were the cause of a tremor. In reporting a case of tumor of the left prefrontal lobe, Mills and Weisenburg¹⁵ say

There were muscular tremors in the hands and legs much like those seen in paralysis agitans. At first they were on the left side only, but toward the end involved the right side also. They were at first partially under control, and by an effort of will the patient could stop them, later he could not, and they occurred also during sleep.

Though this tremor differed in some respects from the tremor of paralysis agitans, it is difficult to see why, if a symptomatic tremor, it should have begun on the same side as the tumor. There are many instances of gross lesions found in the brain which are simply conditions complicating the paralysis agitans, viz Oppolzer¹⁶ found an apoplectic cyst in the occipital lobe accompanied by an ependymitis of the lateral ventricles, especially the posterior horns, v Sass¹⁷ reported a case in which there was an ependymitis of the fourth ventricle. At present the occurrence of gross lesions in the central nervous system in cases of paralysis agitans is regarded as merely a coincidence.

A critical study of the positive pathologic findings in the central nervous system in cases of paralysis agitans reported by numerous investigators leads to the conclusion that they are simply the changes of senility modified occasionally by intercurrent affections or the senile marasmus that is so often the cause of death in these cases. The lesion regarded as specific for the disease by one observer is expressly denied by many others. In most of the cases the lesions described are diffuse and affect various anatomic elements, nerve fibers, nerve cells, neuroglia, the blood vessels, etc., but there is the greatest diversity of opinion as to which is the most affected,

and it is evident that these findings have no constant relation to the disease. Occlusion of the central canal by the overgrowth of the epithelial cells is described by Joffroy,¹⁸ Demange¹⁹ and many others. In the case reported by Murchison and Cayley²⁰ the central canal was widened and filled with leucocytes. In many cases numerous amyloid bodies were found in the spinal cord. Cases are reported as presenting a partial degeneration of the tracts in the white matter of the spinal cord. Burzio²¹ found a light grade of atrophy in many fibers of the crossed pyramidal tracts and of Goll's and Burdach's columns. Dowse²² found degeneration of only one lateral column. Sanders⁸ found "a somewhat diffuse degeneration of nerve fibers in the spinal cord, but especially in the direct and crossed pyramidal tracts." Most investigators expressly deny the existence of any degeneration in the spinal cord, and in the 14 cases studied by me I was unable to detect any degeneration in the Marchi methods of staining.

Many writers have described changes in the neuroglia in paralysis agitans. Schultze speaks of a chronic "epitomeningitis and chronic interstitial myelitis." Murchison and Cayley found thickening of the subpial neuroglia layer with extension of the proliferation into the cord and islets of sclerosis scattered throughout the spinal cord by either the Weigert hematoxylin or the cord, especially in the dorsolumbar region and more in the posterior root entrance zone. Demange,¹⁹ Joffroy¹⁸ and Dubief²³ report similar findings. Koller¹⁶ found practically the same in his case, but questions whether we can draw a line between this proliferation and the neuroglia increase in senility. In paralysis agitans the neuroglia overgrowth, he thinks, was more marked in the lateral and posterior columns, and he considers it to be the primary change, which by interfering with the lymph circulation causes secondary alteration of the nervous elements. Redlich²⁴ lays great stress on the increase of glia tissue which he found, especially about the blood vessels, forming small islets which had a tendency to become confluent and form larger islets. This perivascular sclerosis occurred chiefly in the antero-lateral columns, and the stiffness of the muscles and the tremor, in his opinion, are due to a functional disability ("schwäche") of the nerve fibers. Somewhat similar findings are described by Wollenberg,¹ Borgherini²⁵ and Sanders,⁸ but the last two mentioned found the neuroglia proliferation more marked in the gray matter than in the white. Sanders especially emphasizes this as being a different condition than that found in senility. He found not only a comparatively greater increase in the amount of neuroglia tissue in the anterior horns but also numerous spindle cells ("spinnenzellen") in both cases of paralysis agitans and cases of senility with a marked tremor. He explains the tremor and also the difficulties in gait by assuming that this glia overgrowth interferes with the connection between the upper and lower motor neuron. As contrasted with these findings, Dana²⁶ describes a very moderate increase in the connective tissue within the cord and none of the islets of neuroglia described by Redlich.²⁴

26 Am Jour Med Sci., Novemb

Pathologic changes in the blood vessels of the central nervous system are described by many writers on the subject. They are generally of the arteriosclerotic type, but in some cases are described as peculiar either in character or distribution. Burzio²¹ found the blood vessel walls thickened, especially in the neighborhood of the neuroglia overgrowth, and Sanders emphasizes this relation. Sanders found also that the finer capillaries were more affected than the larger, a fact which has been noted by Joffroy,¹⁸ v Sass¹⁷ and by Murchison and Cayley²⁰. The last named and also Ketscher²⁷ found milary hemorrhages here and there in the spinal cord. J. R. Hunt²⁸ found that the blood vessels in the spinal cord were increased in number and there was a universal cellular infiltration about them which, when stained by Ehrlich's method, proved to consist of escaped leucocytes. Mihary aneurisms were seen in the spinal cord by Borgherini,²⁵ Ketscher²⁷ and Sanders.⁸ Carrayou²⁹ found varicosities of the veins in the medulla with small areas of softening in the oculomotor root and pyramidal tracts, and he explains the clinical symptoms of the disease on the ground that these lesions interfere with the passage of the nervous impulses. Redlich²⁴ speaks of a hyaline degeneration of the blood vessel wall with an especial thickening of the media and a proliferation of tissue about the blood vessel which fills up the perivascular spaces. These changes, he affirms, were much less marked in the medulla oblongata and were not there accompanied by the perivascular sclerosis. Dana²⁰ could discover no special thickening of the walls of either the veins or arteries in his case. Borgherini²⁵ found changes in the sympathetic ganglia, degeneration of the cells with an overgrowth of the interstitial tissue.

Philip³⁰ found degenerated Betz cells in the paracentral lobules. The change consisted in a diffuse staining of the cells and a similar though less marked condition was noted in the motor cells of the anterior horns of the spinal cord. His finding is the only direct pathologic evidence I could discover bearing out the oft repeated assertion (Gowers,³¹ Bychowski³² and others) that paralysis agitans is a disease of the cerebral cortex. Gordinier³³ found changes in the motor cells of the cerebral cortex, but not so marked there as in the spinal cord. The Golgi stain showed the dendritic processes nearly normal.

The condition of the anterior horn cells of the spinal cord has been noted as normal in some of the cases to which reference has already been made (Redlich,²⁴ Wollenberg¹ and others). In a large number of cases the anterior horn cells were found to contain an excessive amount of yellow pigment (Dubief,²³ Dowse²² v Sass,¹⁷ Hunt,²⁸ Borgherini,²⁵ Herterich,¹³ Joffroy,¹⁶ Ketscher,²⁷ Gordinier,³³ Luys³⁴ (of the medulla oblongata), Sanders⁸ and others). Joffroy³⁵ and Demange¹⁰ describe also a pigmented condition in the cells of the column of Clarke. Gordinier³³ also noted this but found it less marked than in the anterior horn cells. Distinct degenerative changes in the anterior horn cells are described by Demange,¹⁰ Koller,¹⁶ F. Burzio,²¹ Caterina,³⁶ Hunt,²⁸ Gordinier³³ and Dana.²⁰ The changes described as present in these cases differed somewhat, but were gener-

ally a chromatolysis, with a loss or displacement of the nucleus of the cell, atrophy of the cell, vacuolation of the cell, tumefaction of the nucleolus, etc. Dana²⁰ lays great stress on diminution in number and pathologic changes in the dendritic processes of the spinal motor cells, with a consequent diminution in richness of the dendritic plexus in the anterior horns. He found this lesion most marked in the lower cervical and first dorsal segments (corresponding to the beginning of the tremor in his case), next in the midcervical, then midlumbar, upper sacral and least in the middle and upper dorsal. The brain cortex showed slight degeneration of the cells. It should be remembered that Dana's case was complicated by sarcomatosis, and death was due apparently to exhaustion, and that in such cases a tumor toxin is probably present which produces chromatolytic and degenerative changes in the nerve cells.

No pathologic changes in the cerebellum were noted by Dowse,²² v Sass,¹⁷ Borgherini,²⁵ Redlich,²⁴ Hunt,²⁸ Gordinier³³ or Dana,²⁰ except participation to a moderate extent in a general arteriosclerosis. Hunt²⁸ and Gordinier³³ found the spinal nerve roots normal. Dana²⁰ found them greatly congested, and by Borgherini²⁵ and Redlich²⁴ they were found slightly degenerated.

A long list could be made of cases in which the pathologic examination of the central nervous system was negative. Thus Koller¹⁶ cites the cases of Petrus,³⁷ Olliver,¹⁶ Cohn,³⁸ Charcot,³⁹ 3 cases, Westphal,⁴⁰ Simon,¹⁶ 4 cases, Bauer,⁴¹ 2 cases, Leroux⁴² and Weinkowitz.⁴³ To these may be added the case of Oppenheim,⁸ in which he found only a "questionable" staining of the columns of Goll. Furstner⁹ mentions specifically that there was no pathologic condition present in the brain or spinal cord of his first case, the blood vessel walls were not thickened and there was no increase of the neuroglia nor changes in the nerve cells. His patient was 61 years of age and had the disease for five years. Schwenn⁴⁴ reported a case of a patient who died at the age of 43½ years and was therefore no senile. He says "I found neither in the brain nor spinal cord any pathologic changes." Idelsohn⁴⁵ and Blocq⁴⁶ also report cases in which there was no pathologic change in the central nervous system.

Various changes have been observed in the peripheral nerves. Borgherini²⁵ found in the vagus, median and external tibial nerves a hyperplasia of the interstitial tissue and increased vascularity. Skoda⁴ found thickening of the neurolemma in the nerves of the upper extremities. Joffroy reported a case in which paralysis agitans was combined with a peripheral neuritis, and Follet and Marquis⁴⁷ report *Un cas de maladie de Parkinson fruste, peut-être d'origine polynévritique*. Their paper is inaccessible to me. Borgherini,²⁵ Redlich,²⁴ v Leyden⁷ and Ketscher²⁷ have noted an increased amount of the interstitial tissue in the nerves, and by the last-named the nerves were also found degenerated. Blocq,⁴⁶ who examined the peripheral nerves, both in the fresh state and after hardening, found nothing abnormal. Dana²⁰ also

ORIGINAL INVESTIGATIONS THE NERVOUS SYSTEM

I have had the opportunity of examining the pathologic material from 14 cases of paralysis agitans, in 8 of which I was able to study the peripheral nerves and muscles and in 2 of them also the ductless glands. That 14 cases with necropsy is a very large number will be better appreciated when it is remembered that Gordinier,²³ writing in 1899, could find reported but 54 cases with necropsy in the whole literature of the disease, and of these only 24 had been examined histologically. The largest number of cases with necropsy reported by any single observer is 4. Details of the positive pathologic findings in 14 cases with necropsy, in 12 of which there is also given an abstract of the clinical histories, will be found in the appendix.

The ages of the patients at death, in the cases that I have examined, ranged from 45 to 75 years, the duration of the disease from two to twenty years.

Macroscopic examination of the central nervous system, including trans-sections, revealed lesions in only one case.

The tissues are preserved in formaldehyd solution (10 per cent), or in Müller's fluid. In making the microscopic examination of the central nervous system pieces of tissue were taken from each paracentral lobule, the pons, the vermis of the cerebellum, the medulla oblongata and from the cervical, thoracic and lumbar regions of the spinal cord. The anterior and posterior spinal nerve roots from the lumbar and cervical regions were examined separately from the cord in 6 cases, the posterior root ganglia, from the lumbar region, in 2 cases, the peripheral nerves were examined in 8 cases. The pieces were dehydrated in alcohol in the usual manner, imbedded in celloidin, and the sections stained as follows: Thionin modification of the Nissl method for study of the nerve cells; the Weigert hematoxylin and the Marchi osmic acid for degeneration, the hemalum-acid fuchsin, and the Mallory neuroglia stains.

A summary of the findings in my cases shows that the most constant lesion was a fibrosis of the capillary blood vessels of the spinal cord, which by rendering them more prominent, caused an apparent increase in their number. The region of the posterior and lateral columns seemed to be the most affected. This lesion was present in eleven cases, in all of which it was an accompaniment of a general sclerosis of the blood vessels of the nervous system. The next most frequent finding was a diffuse overgrowth of the glia in the spinal cord, usually more marked in the posterior columns, in six cases. It was not confined to any system of fibers and in but one case did it show the tendency to form islets about the blood vessels as described by Redlich.²⁴ In no case was it demonstrated that the neuroglia proliferation was more marked in the gray matter than in the white matter. The Betz cells of the paracentral lobules were considerably pigmented in many cases but only in four cases was the pigmentation very marked, and in only two cases were there any distinctly degenerated cells. The motor cells of the anterior horns of the spinal cord were excessively pigmented in six cases, in four cases they showed distinct chromatolytic changes in some of the cells but the loss of the dendritic processes with a consequent lessening of the richness of the dendritic plexus, as described by Dana, was not observed. Recent hemorrhages into

the anterior horns of the spinal cord were observed in two cases, they were probably agonal. The perivascular spaces were widened in four cases, and in five cases numerous amyloid bodies were seen in the spinal cord, especially in the posterior columns. The central canal was closed in eight cases, dilated in one case, double in one case, but probably these are to be regarded as normal conditions. The cerebellum, pons and medulla oblongata were practically normal in all the cases in which they were examined, a moderate sclerosis of the blood vessels and a slight subpial proliferation of the neuroglia not being considered pathologic when found in aged persons. In one case there was a round cell infiltration of the pia. The anterior and posterior spinal nerve roots in the cervical and lumbar regions were found congested in two cases, but not in any case degenerated. There was no degeneration of the nerve fibers of the cord in any case, but the neuroglia proliferation, in six cases, gave the posterior columns the appearance of staining lighter than the rest of the cord by the Weigert hematoxylin stain. The peripheral nerves were examined in eight cases, in two they appeared degenerated when stained by the Weigert hematoxylin stain, in two others there was a swelling of the myelin sheaths, accompanied in one case with swelling of the axis cylinders. The intramuscular nerves, even those within the muscle spindles, stained well with the Weigert hematoxylin stain. The nerves showed no degeneration when stained by the Marchi method.

DISCUSSION OF THEORIES OF THE NERVOUS ORIGIN OF THE DISEASE

Many theories have been advanced as to the nature and location of a lesion in the central nervous system in paralysis agitans. Some have been purely hypothetical and based entirely on the clinical symptoms, others on the findings in the few cases examined by their authors. Gowers²¹ expresses his view thus:

Paralysis agitans must be regarded as a chronic senile change in the nutrition of the terminations of the branching processes of the dendrites of the motor nerve cells of the cortex causing constant liberation of nerve energy to be increased and also causing a change in the form, uniformity gives place to rhythmical liberation.

Bychowski²² and others hold similar views. The arguments advanced in support of this are: 1. A hemiplegic distribution of the tremor speaks for a cortical origin. Numerous cases have been reported in which the symptoms involved both arms or both legs, or in other words, were paraplegic. By Hart (1 c) they were found to be as frequently paraplegic as hemiplegic. 2. The tremor ceases during sleep (1 c), when the function of the hemisphere is least active but in cases in which tremor is known to be due to cortical involvement (case of Mills and Weisenburg, 1 c) the tremor does not disappear during sleep. 3. When a case of paralysis agitans in which all four extremities are affected develops a hemiplegia, the tremor disappears on the paralyzed side. Such cases are said to have been observed by Gowers²¹ Weisenburg²⁰ and Grashay.⁴³ This if invariably true proves that the nervous impulses which by their perversion cause the symptom originate in the cerebral cortex, but it does not prove where the perversion of impulse in this disease takes place. Whether in origin transmission or in their reception ultimately by the muscles, the cause of a complete cessation of the impulse is not known. Hart reports a case in which the

the paralyzed side after a hemiplegia and was apparently unaffected by it

Bychowski³² adds the following reasons 4 The not uncommon combination of insanity, hysteria or brain disease with paralysis agitans Most authors regard this combination as decidedly uncommon 5 The parasthesiæ and subjective sensations of heat and cold These are generally considered as accompanying peripheral rather than cortical conditions 6 The constant failure of any change in the sphincter reflexes This is of some importance as differentiating a spinal from a cortical origin, but would have no bearing if the lesion is outside the nervous system 7 The increased knee jerks The knee jerks in paralysis agitans are too variable to be used as an argument on which to base a pathology of the disease

Cuyhls⁴⁰ considers the tremor of paralysis agitans as cortical in origin, and holds that the lesion consists of retraction of the dendritic processes of the cells and draws analogies to tremor seen in paresis, alcoholism, etc There is no pathologic evidence to support the theory of a cortical origin for the disease except the findings of Philip³⁰ Brissaud⁶⁰ believes that a lesion of the locus niger is the cause of the disease Tremors are produced by lesions in this region, but they are different from that of paralysis agitans and are not accompanied by the other symptoms of the disease Valery⁵¹ considers that paralysis agitans is a syndrome due to a lesion in the mesencephalon, the syndrome being more or less complete, according to the extent of the lesion However, lesions of the mesencephalon are not found at necropsy

Ballet⁵² and also Dana,²⁰ from pathologic evidence furnished by their own cases, place the chief lesion in the motor cells in the anterior horns of the spinal cord Ballet,⁵¹ as a breaking of the processes, particularly the dendritic processes Dana²⁰ holds that

There is early functional disturbance and later a degeneration and destruction of the dendrites of the anterior horn cells which interferes with the even flow of motor impulses, and finally leads to motor weakness and rigidity, owing to the cell being practically cut off from the brain

From a pathologic standpoint this theory is not confirmed by any other observer, although especially looked for in my cases Clinically, it would seem that a tremor due to such a lesion, "which interferes with the even flow of motor impulses," would be rather of the intention type, and unlike that of paralysis agitans which momentarily disappears on voluntary movement

Redlich²⁴ believes that the overgrowth of the neuroglia in islets about the blood vessels in the lateral and posterior columns of the spinal cord accounts for the tremor and rigidity on the grounds of a functional weakening of the nerve fibers in their vicinity, thus producing a special type of dorsolateral sclerosis The rigidity of paralysis agitans, however, is very different from the spasticity due to lesion of the lateral column, and the pathologic findings of Redlich are not confirmed, indeed, are expressly denied by other observers (Dana²⁰) I found a diffuse overgrowth of the neuroglia in the lateral and posterior columns in a number of cases, but not in the form of islets about the blood vessels except in one case

Gordinier³³ explains the tremor and rigidity as follows

The characteristic symptoms of this disease are due to one and the same cause, namely, an irritation from the presence of an increased amount of neuroglia in the posterior columns producing an excitability of the reflex collaterals of the posterior nerve roots arborizing about the ventral cornual cells which results in an increase in the normal rhythmic discharges of energy from those cells, producing at first the tremor and later the rigidity

Gordinier's case, the pathology of which is the basis of his hypothesis as to the causation of tremor and rigidity, was "a typical case without tremor"

Sander⁸ thinks that the overgrowth of glia in the anterior horns by interfering with the connection between the upper and lower motor neuron, is the cause of the tremor and the difficulties in gait He examined the central nervous system from cases of senility with and without tremor and also paralysis agitans, in the cases of paralysis agitans and in those seniles in whom tremor had been marked, he found a special predilection of the glia proliferation for the gray matter This theory of Sander⁸ takes no account of the clinical difference between paralysis agitans and senile tremor, and his pathologic findings lack confirmation

From the above summary it will be seen how diverse and contradictory are the pathologic findings in the central nervous system in paralysis agitans, but the explanation for this is simple Paralysis agitans is a disease that in almost every case begins late in life and is not rapidly fatal There are changes which occur in the central nervous system, as they do in other parts of the body with the advance of years, changes that are well known, though perhaps not well understood, and which consist, to state it in a few words, of a gradual replacement of the parenchymatous structure by the connective tissue of the part, in the nervous system by the neuroglia This change is modified, advanced or retarded, to an extent, by the mode of life, heredity, disease, etc Arteriosclerosis is usually found at this period of life, and also the incidence of wasting diseases and malignant new growths, which, by their toxic influence, are known to produce degenerative changes in the central nervous system These changes, the changes of senility variously modified by the other factors of which I have spoken, are the most constant findings in the central nervous system in paralysis agitans

Many men (Wollenberg,¹ Campbell,⁵³ Nonne⁵⁴ and others) have found changes similar to those found in paralysis agitans, in the spinal cords of seniles who during life had shown none of the symptoms of that disease. To reconcile this similarity in the findings with such distinct clinical differences, it has been held that the lesions in paralysis agitans are of precocious onset and exaggerated intensity, such a view is held by Dubief,²³ Jacobsohn,⁵⁵ Borgherini²⁵ and Ketscher²⁷ Against this, however, are the findings of Furstner,⁹ who found no marked senile changes, Idelsohn,⁴⁶ and Schwenn,⁴⁴ whose patient died at 43½ years, and was therefore not a senile

That paralysis agitans is but senility, even though a precocious or special form of senility, I believe, with Dana,²⁰ "is contrary to all clinical experience" The lesions of senility found in the central nervous system in many cases are but natural when we consider the age of the patient at necropsy, and the same lesions are found in many seniles not the subject of the disease, while in those patients who die at an earlier age these changes

are not found. Therefore, from a pathologic standpoint also, paralysis agitans and senility must be regarded as two different conditions.

THE CHANGES IN THE MUSCLES

Oppenheim⁵⁶ gives as the characteristic symptoms of this disease tremor, muscular rigidity, which produces a peculiar position of the head, trunk and extremities, retardation and difficulty in active movements and a peculiar modification in gait. The last two are the result of the former, so that really we have two, muscular rigidity and tremor. According to the same author, even the subjective symptoms are due to the muscular rigidity and limitation of active motility. Cases have been reported without tremor, so that it would seem that the muscular rigidity and its peculiar manifestations is the one absolutely characteristic symptom. This rigidity is very different from spasticity, it is not under the influence of the will, is not increased by passive movement, nor is it affected by the mental state of the patient, and it is constantly, gradually progressive, all of which speaks for a muscular affection. Blocq⁴⁶ was probably (so quoted by Redlich²⁴ and by Raymond⁵⁷) the first to formulate the theory of a myopathy as the anatomic basis of the rigidity. He found distinct anomalies in the muscles, irregular atrophy and hypertrophy of the fibers, and proliferation of the sarcolemma nuclei. Joffroy³⁵ had already noted similar changes in the muscles, and Borgherini²⁵ had observed "that in the muscle the connective tissue was increased, the muscle fibers were all somewhat delicate and some were intensely atrophied, showing vacuoles and increase in the number of sarcolemma nuclei." Burzio,²¹ Redlich,²⁴ Pierret and Vesselle,⁵⁸ Wollenberg,¹ v. Sass¹⁷ and others found similar changes in the muscles, and by Skoda,⁴ E. Leyden⁵⁹ and Ketscher²⁷ these changes were found combined with a fatty degeneration of the muscles. Dana²⁰ found a fatty degeneration of the muscle which he decided could not be due to neuritis, for the nerve supplying that muscle was normal. In Gordinier's³³ case the muscle was apparently not examined, as he makes no mention of it, and this unfortunately is true in many of the cases reported with necropsy.

Schwenn⁴⁴ described changes in the muscles in his cases similar to those previously described, but called attention to the fact that the changes were not the same in all parts of the muscle, but were at various places at various levels. He comes to the conclusion, on the ground of his own investigation, that the basic anatomic change in paralysis agitans is a severe progressive disease of the muscle which gradually involves the whole musculature. He calls attention to the fact that evident changes are found in the muscles during life, and cites Blocq⁴⁶ and Borgherini²⁵ as having found changes in the electric irritability of the muscles. Mendelsohn⁶⁰ observed an increase in the latent period in the diseased muscles. Schwenn⁴⁴ also noted the resemblance to myotonia congenita, "in which many specific changes in the muscles are found," and also that the most common etiologic factors affect the muscles, trauma, strain, excessive use, etc. Schiefferdecker⁶¹ by his very careful pathologic studies, in which comparisons were made with normal con-

trol tissue and all the factors of postmortem rigidity, method of hardening, etc., were taken into account, concludes that

Both myotonia congenita and paralysis agitans are diseases of the sarcoplasm and fibrillae of the muscles. In paralysis agitans, however, there is also a disease of the muscle fibers in the muscle spindles, although the nerve fibers both within and without the muscle spindles are normal.

Idelsohn⁴⁵ describes his findings in the muscles as similar to those of Schiefferdecker,⁶¹ increase in the number of sarcolemma nuclei, hyaline degeneration, swelling of the fibers with vacuolation, etc., and concludes that the anatomic lesion of Parkinson's disease is in the muscles.

I was enabled to examine muscular tissue from 8 of the 14 cases with necropsy, in one other case a piece of muscle was removed from the forearm of a patient in the service of Dr. W. G. Spiller at the Polyclinic Hospital. The patient (E. W.) was 62 years old and had had paralysis agitans about three years. The symptoms of the disease were typical, but otherwise the patient was in good health, and the muscle was removed by me for the purpose of this examination only. I know of but two instances in the literature in which muscular tissue has been removed from the living patient for this purpose. DeBuck and DeMoor,⁶² quoted by Raymond⁵⁷ and Sanna Salaris,⁶³ "Note di istologia patologica (per biopsia) sulla fibra muscolare striata nel morbo di Parkinson." The original of these papers in each instance is inaccessible to me. In all I have examined the muscles from 9 cases of the disease and pathologic changes were present in every case.

A summary of the condition of the muscles is as follows:

Many of the muscle fibers were swollen, and in cross-section were round instead of having the normal polygonal shape. There was a marked increase in the number of nuclei within the fibers, many of which were smaller, denser and rounder than the normal. These nuclei were frequently in pairs or in long chains. In several cases the fibers showed atrophic changes, and in these cases, usually of long-standing disease, there was an overgrowth of the connective tissue. In many cases the fibers had a hyaloid appearance and the longitudinal striations were unusually well marked, and in many of the fibers there was a tendency to longitudinal cleavage. In one case trichina spiralis was found in the muscle and in this case, in addition to the above described changes there was an intense interstitial myositis and also a discoidal degeneration of the muscle fibers. Muscle spindles were hard to find in the sections from any of the cases, but in those examined the muscle fibers within them showed similar changes to those surrounding them. The nerve fiber within the spindle was normal, and the intramuscular nerves showed no degeneration when stained with the Weigert hematoxylin stain. These pathologic changes were not of the same intensity in all the muscles nor in different parts of the same muscle.

My findings in the muscle agree generally with those of Schwenn⁴⁴, Schiefferdecker,⁶¹ and Idelsohn⁴⁵ and indicate a definite and probably a specific change in the muscles in paralysis agitans, though the latter can not be regarded as proven. Schiefferdecker⁶¹ regards the lesions as different from those due to overactivity of the muscle. v. Sass¹⁷ examined the muscle of a normal individual 93 years old as a control and

found decided differences between it and the muscle in paralysis agitans. In paralysis agitans the fibers were filled with nuclei, and the small, round, dark-stained nuclei were particularly increased. In the muscle of old age there was an increased number of spindle-shaped and large oval nuclei, but the small dark nuclei were absent.

In a case of paraplegia due to peripheral obliterating arteritis in which I examined the muscles of the legs, I found differences from those in paralysis agitans in the increase of interstitial tissue and in the predominance of the rod-shaped nuclei over the small round nuclei. The fatty degeneration of the muscle fibers found by Skoda,⁴ Dana²⁰ and Ketscher²⁷ was found by the last named also in several patients with arteriosclerosis. I found it present in a case of triplegia following hemiplegia reported by Dr. Charles W. Burr and myself before the American Neurological Association, June, 1906, and in this case it was regarded as due to the lack of nutrition to the muscles from shutting off of the blood supply by an intense peripheral arteriosclerosis. There is not enough known of the pathology of the muscles to say that these changes described are specific in paralysis agitans, but they are co-existent and probably co-extensive with the symptoms rigidity and tremor, though it can not be definitely proven that they are the cause of these symptoms. By some, the changes are regarded as caused by the tremor, the constant contraction of the muscle. But in studying the pathology of disease of other organs of the body we usually attribute the functional changes observed to the lesion that is found if that lesion is adequate to explain the symptoms.

Can we explain the symptoms of the disease by the anatomic findings in the muscles? The onset of the disease is usually gradual, with a gradual progression from muscle to muscle and from part to part, though it follows no regular course, sometimes being hemiplegic, sometimes paraplegic. In this it resembles the rheumatic joint affections more than any other disease, and indeed it has been supposed to be due to similar toxin. Occasionally the onset of the tremor is sudden, but this is explained on the theory of a muscular affection in the same way that a sudden onset is explained by those who hold the opinion that the disease is due to overgrowth of the neuroglia in the cord, etc., and that is that the prodromal symptoms had gone unnoticed. The most characteristic symptom of the disease is the muscular rigidity, and on this symptom most of the other symptoms depend. In the course of the disease it gradually increases and extends in limits so as finally to involve all the muscles in the body except the unstriated. It is not spasticity, the resistance is the same whether the limb be moved quickly or slowly. It has something of the complete loss of life or elasticity that is felt when a lead pipe is bent. I have found a quantitative change in the irritability of the muscle to the Faradic current in several cases in which the disease was of long duration. "The electric irritability is little affected except toward the end, when there is a quantitative change" (Wollenberg). This, however, is no argument against a local affection of the muscles, as in the muscular dystrophies the electric irritability is equally little affected. The tendon reflexes are usually normal in both diseases, unless the muscles concerned in the reflex become implicated, and the cases in which they are exaggerated in paralysis agitans really prove nothing, since seniles without symptoms of paralysis agitans often show increased knee jerks. All the clinical evidence points to the rigidity as being due wholly to an affection of the muscles. Actual paralysis

is very rare in paralysis agitans, and when it occurs is usually limited to one muscle, as in the case reported by Noncorge⁶⁴ of complete paralysis of the right serratus magnus.

Schaefferdecker⁶¹ and others suggest that the pathologic change in the muscle spindles is the anatomic basis of the tremor. It is a very important point that the changes in the muscles in paralysis agitans differ from those found in myotonia congenita only in an involvement of the muscle spindles in the former and not in the latter. Sherrington⁶⁵ says that the muscle spindles are undoubtedly sensory end organs, and Schaefferdecker⁶¹ quotes Baum⁶⁶ as stating that they are organs of muscle sense. Langerhans⁶⁷ comes to the conclusion that they are organs of muscle sense, and that they cause or regulate the muscle tone. As it is generally admitted that the tremor in paralysis agitans is due to a pathologic condition which affects the neuromuscular mechanism that maintains muscle tone, the lesion of the muscle spindles affords a reasonable explanation of the tremor. Another important point tending to prove that there is a relation between the tremor and the lesion of the muscle spindle, and one that I have not seen noted elsewhere, is that the tremor almost always begins in the muscle where the muscle spindles are most abundant, and does not affect those muscles which contain no muscle spindles. Both Millbacher⁶⁸ and Frankel⁶⁹ found the muscle spindles to be most abundant in the muscles that move the thumb. Batten⁷⁰ found them most abundant in the small muscles of the hand and in the biceps. They were not able to find any in the diaphragm or in the masseter muscles. Siemerling,⁷¹ in a case of gumma of the base of the brain, described a rather doubtful muscle spindle in the inferior rectus muscle in one eye, but neither Millbacher, Frankel, Batten nor Sherrington could find any spindles in the ocular muscles, though Sherrington found tendon organs there. William Hirsch,⁷² writing on paralysis agitans in Posey and Spiller's "The Eye and the Nervous System, Their Diagnostic Relations," says

To the tremor would apparently correspond nystagmus but this symptom has never been observed in paralysis agitans. This fact furnishes another proof for the assumption that nystagmus is produced by some central lesion and not by a disturbance in the general muscular tonus, because if the latter view were correct we would be bound to observe the symptom at least occasionally in paralysis agitans.

Inferentially, therefore, the tremor in paralysis agitans is due to a disturbance of muscular tonus, which is not operative in the ocular muscles, and the only apparent reason why it should not do so is because of the absence of muscle spindles. M. Koenig,⁷³ Debove⁷⁴ and Galezowski,⁷⁵ writing on the visual or ocular symptoms of paralysis agitans, describe rigidity of the ocular muscles and difficulties in movement due to this rigidity, but do not describe any thing that corresponds to the typical tremor as it occurs in the extremities. Batten⁷⁰ states that he could find no muscle spindles in the intrinsic

muscles of the tongue Forster⁷⁶ found them in the hinder part of the tongue, which muscles, when the two sides act in unison, protrude the tongue and draw it back. The usual tremor of the tongue in paralysis agitans on protrusion is a piston-like forward and backward movement, and thus here again the peculiar distribution of the muscle spindles bears an apparent relation to the muscles affected by the tremor. The tremor of paralysis agitans has certain peculiarities that are easily explained on the ground that it is due to an affection of the muscle spindles, and in much the same way as they are explained by those who hold that the lesions in the cord are responsible for the tremor. In either case it is admitted that the tremor is due to interference or a change in the impulses that maintain or regulate muscle tone, so that the tremor stops when the muscles are relaxed in sleep, or when a hemiplegia stops them completely on the paralyzed side, or when the impulse for a voluntary act supersedes, momentarily, the regular reflex.

Many of the symptoms of paralysis agitans are easily recognized as due to the muscular tremor and the muscular rigidity, such as the peculiarities in gait, the position the facies, the ocular symptoms, etc. Other symptoms that are not so obviously due to the two primary symptoms are seen to be so on a careful analysis, thus Catola⁷⁷ comes to the conclusion that the salivation is due first, to tremor of the lips, cheeks and tongue, second, to rigidity of the same organs and of the muscles of the pharynx, with more or less complete interference with the movements of deglutition. The recumbent position of the patient permits the saliva to descend to the posterior part of the pharynx and so stimulates the reflex for deglutition. Other conditions often arise in paralysis agitans which are by some regarded as symptoms, but which might more reasonably be looked on as complications. M. A. Soques⁷⁸ has recently called attention to the syndrome of labioglossolaryngeal palsy occurring as a symptom of paralysis agitans, and quotes Bruns⁷⁹ as having found it in 4 cases in 74. There are not the characteristics of a true bulbar palsy, but rather a pseudo-bulbar palsy. Dejerine, in a discussion of this paper, considers the syndrome as a complication and called attention to the fact that many patients with paralysis agitans also have arteriosclerosis and are in a condition favorable for the production of a pseudo-bulbar palsy. The paresthesiae, the sensations of heat and cold might well be considered as complications due to the age of the patient rather than symptoms of the disease. In an analysis of 219 cases, Hart⁸⁰ found sensations of heat in only 31, sensations of cold in 20, and both kinds in 20. Sensations of heat and cold are not at all uncommon in many people of advanced age.

It may be that the same factor which produced the changes in the muscles also makes itself felt in other ways, in producing a thickening or a loss of elasticity in the skin, for instance Frankel⁸¹ in calling attention to the loss of elasticity of the skin in paralysis agitans says "that perhaps the muscle fibers are altered by the same influence." A. M. Luzzato⁸¹ found that in a case of paralysis agitans combined with a scleroderma both were improved for a time by the administration of arsenic. A histologic examination threw no light on the pathogenesis of the condition, but he

concludes that it was a double expression of one morbid state.

THE PATHOGENESIS OF THE DISEASE

Two general hypotheses may be considered as to the underlying cause of the changes in the muscles. First, there may be a primary degeneration of the muscles themselves, an abiotrophy, affecting the muscles analogous to that in the muscular dystrophies. Beginning in a muscle frequently after some slight local exciting cause it gradually progresses from part to part. It may well be that people are born with muscles which lose their elasticity more quickly than the muscle of other people, either by use or through other causes that we know little about. The property of elasticity of a muscle has been shown experimentally to be lost by over-extension and is subject to various influences.

A second hypothesis is that there is a toxin circulating in the body which causes these changes in the muscles. The idea of a toxin as the underlying pathogeny of the disease has been widely held. Dana⁸² says

Perhaps the primary infection in paralysis agitans is some autochthonous poison allied to that of rheumatism, at any rate there is no other preceding history that is so often obtainable as that of rheumatism, and there are many facts in the clinical history of the disease which suggest a relationship between paralysis agitans and that form of rheumatic manifestation which is known as rheumatoid arthritis.

Spiller⁸² has called attention to the points of resemblance between paralysis agitans and rheumatoid arthritis.

The examination of the excretion in paralysis agitans has produced some results of interest. Gauthier⁸³ found an increase of phosphoric acid in the urine in cases of paralysis agitans which suggested to him that the muscular changes may be due to an excess of the same in the muscles. His conclusions were that

The symptoms are due exclusively to the changes in the muscular system and derived from the muscular rigidity. This rigidity, the most important phenomenon of the disease, is produced in the muscles without the intervention of the nervous system and is due to an excess of phosphates.

Cheron⁸⁴ had called attention in 1877 to the increased amount of phosphates in the urine, but by him they were considered as affecting the central nervous system, and so producing the symptoms of the disease. G. Gurtler,⁸⁵ C. A. Ewald,⁸⁶ Giovanni Setti⁸⁷ and Decombrel⁸⁸ found no increase of phosphates in the urine. Researches in the contents of the urinary excretion in paralysis agitans have also been carried out by Mosse and Baul,⁸⁹ who found an increase of the completely oxidized phosphates, but a corresponding diminution in the incompletely oxidized, and by J. Leva⁹⁰ and R. Bandiero,⁹⁰ who found it negative.

In poisoning by phosphorus (Siemerling,⁹¹ also Langethans⁹¹), the muscle fibers within the muscle spindles are affected, as well as those outside, which is similar to the effect produced in paralysis agitans. It may be well here to call attention to the remarkable immunity enjoyed by the muscle spindle in various

nervous affections, even when the muscle itself is severely atrophied or even in primary muscle affections, such as the muscular dystrophies. Roth⁹² found them normal in a case of alcoholism, a case of progressive muscular atrophy, and in a woman who died of inanition consequent on a pyloric stenosis. Siemerling,⁹³ in a case of spinal neuritic muscular atrophy, in which he found an intense atrophy of the muscles and a complete degeneration of the intramuscular nerves, found the muscle spindle "entirely unchanged." Blocq and Marinesco⁹⁴ found them present in cases of poliomyelitis and polynuritis when there was total degeneration of all the other muscle fibers. Spiller⁹⁵ found them normal in a case of intense progressive muscular dystrophy with contractures, in which there was no other normal muscular tissue. Grunbaum,⁹⁶ in a case of pseudo-muscular hypertrophy, with great changes in the muscles, found that both muscles fibers and the nerve within the spindles were normal. V. Horsley⁹⁷ found the muscle spindles merely shrunk after division of the nerve in dogs. This immunity of the muscle spindle in degeneration of the muscle consequent on nervous lesions and in the ordinary muscular dystrophies is in marked contrast to the decided effect produced by toxic substances, but there is not sufficient evidence, and what there is is too contradictory to uphold the opinion of Gauthier that the degeneration of the muscles and muscle spindles in paralysis agitans is due to phosphoric acid or one of its compounds. The idea that it is due to some toxic substance, however, receives confirmation.

Under the head of circulating toxic substances may be classed defective or changed internal secretions. Fibrous changes in the ovaries or testicles are regularly found at necropsy in cases of paralysis agitans, but they show no differences from the changes of senility, which in all probability they are. The extirpation of the testicles or ovaries produces no symptoms in any way similar to paralysis agitans, and the injection of such substances as Brown-Sequard extract, on purely empirical grounds it would seem is, so far as I know, of no benefit in this disease. Moebrus,⁹⁷ in 1883 (quoted by Raymond⁹⁷) reported a case of paralysis agitans combined with Basedow's disease and opined that paralysis agitans was due to an alteration in some glandular secretion. Lundborg⁹⁸ reported a case of paralysis agitans combined with myxedematous symptoms, and at necropsy found atrophy and cystic changes in the thyroid, which led him to believe that the thyroid gland plays an important part in paralysis agitans. Langerhans⁹⁷ found that in cretins there was a fatty degeneration of all the muscles except the tongue, cricothyroid, thyrohyoid, and rectus abdominus muscles which was similar to the general fatty degeneration of the muscles seen in phosphorus poisoning and in which the muscles fibers in the muscle spindles also took part. Askanazy,⁹⁹ in a pathologic study of Basedow's disease with special reference to the muscle changes in the disease, found that the muscles fibers were atrophied and had undergone a fatty metamorphosis, the striations were lost and the fibers appeared homogeneous, there was vacuolation of the muscle fibers and proliferation and degenerative changes in the sarcolemma nuclei. The muscles fibers in the muscle spindles showed

the same changes as those about them. He noted a marked tremor of the hands in his case. Castelv¹⁰⁰ reported pathologic alterations of the thyroid in two cases of paralysis agitans. There are several facts against any change in the internal secretion of the thyroid gland operating as the cause of paralysis agitans. The symptoms which accompany marked disease or even total destruction of the gland are not similar to those of paralysis agitans. Alquier¹⁰¹ has examined the thyroid and adrenal glands from cases of paralysis agitans and found not the slightest alteration. In the two cases in which I had examined the thyroid glands there was a simple colloid degeneration in each case, not accompanied by gross enlargement of the gland, and probably a senile change. Thyroid therapy has generally been barren of results.

The numerous cases reported of a combination of paralysis agitans with symptoms of myxedema or Graves' disease and the fact that the muscle changes observed by Askanazy⁹⁹ are similar to those in paralysis agitans lead to the conclusion that there is some intimate relation in their causes and as a logical result to an investigation of the parathyroid glands. The parathyroid glands have gradually assumed a position of great importance in pathology since their discovery by Sandstrom. They were at first supposed to be accessory or embryonic thyroids. Welch (cited by Richardson¹⁰²) considers that anatomically the parathyroid glands resemble the anterior lobe of the pituitary body, and that unlike the thyroid the presence of a colloid material in the gland is retrograde or degenerative in its nature. Richardson¹⁰² quotes Gley, an early investigator of the subject, as holding the opinion, supported by physiologic experiments, that the parathyroids are glands *suu generis* and have a specific function related to that of the thyroids. That the removal of the thyroids in one case and the parathyroids in another produces very different results is also proven. In a personal communication Dr W. S. Carter, now of the University of Texas, Galveston, from his experiments performed on dogs while at the University of Pennsylvania, concludes that "the parathyroids are more important than the thyroids, that the acute nervous symptoms in dogs which follow total extirpation of both thyroids and all four parathyroids are due to the removal of the latter bodies and not to the former. Total parathyroidectomy without thyroidectomy produces tetany and death just as certainly as the total extirpation of both sets of bodies. On the other hand extirpation of the two thyroids leaving one or two external parathyroids with the circulation intact may cause transitory symptoms from the accidental injury to the parathyroids at the time of operation, but I have had such animals live for months in perfect health. The subsequent removal of the remaining one or two external parathyroids would then produce the characteristic tetany and death within a few days." These results are in accord with those obtained by other investigators.

Richardson¹⁰² gives the acute symptoms in a parathyroidectomized dog as tremor, rigidity, convulsions, dyspnea, and death. With due allowance for the sudden onset and complete removal of the gland in these experiments compared to the more gradual destruction of the gland by a pathologic process, from all the descriptions given, the symptoms presented by a parathy-

roidectomized animal are very similar to those of paralysis agitans. In the picture of a monkey in this tetanic condition (v. Eiselsberg reproduced by Richardson¹⁰²) there are seen many resemblances to the characteristic position of a patient with paralysis agitans: the head and back bent forward, the joints of the extremities in flexion, the general appearance of rigidity and even the ulnar deviation of the hands. So far as I know, Lundborg¹⁰³ in 1904 was the first to call attention to the resemblance between the symptoms of paralysis agitans and the effects of parathyroidectomy in animals, and he arrived at the conclusions that "paralysis agitans is probably a chronic, progressive hypoparathyroidismus." Berkley¹⁰⁴ also noted this similarity in symptoms and reports eleven cases of paralysis agitans treated with parathyroid extract, nine were benefited and he refers to one very early patient who considered himself cured. These results of Berkley assume more importance in throwing light on the pathogenesis of the disease when we recollect the uniformly discouraging results of treatment with the other glandular extracts. Neither Lundborg or Berkley had any pathologic evidence to support their conclusions.

I was able to examine the parathyroid glands from two of my cases, and in the opinion of Dr. Allen J. Smith, professor of pathology at the University of Pennsylvania, they were both in a distinctly pathologic condition. In one there was some colloid material which, according to Welch, indicates a degenerative condition, but in both these cases there was a peculiar infiltration with fat, especially in relation to the blood vessels. This pathologic evidence of disease of the parathyroid in paralysis agitans, when considered together with the experimental evidence quoted and the therapeutic results of Berkley, suggests that the parathyroid glands play an important part in the pathogenesis of paralysis agitans.

CONCLUSIONS

1 Paralysis agitans is not a neurosis nor is it senility.

2 The anatomic basis of the symptoms, muscular rigidity, tremor, and the symptoms dependent on them, lies in the affection of the muscles.

3 The disease itself is probably a general toxemia and there is suggestive evidence that it is due to alteration in the secretion of the parathyroid glands.

I have to thank Drs. W. G. Spiller, Charles K. Mills, Charles W. Burr, James Hendrie Lloyd, Charles S. Potts, D. J. McCarthy, T. H. Weisenburg, and J. H. W. Rhein for referring to me the pathologic material on which this research is based, and especially to thank Dr. William G. Spiller and Dr. Allen J. Smith for verifying the pathologic findings.

DISCUSSION

Dr. D. J. McCarthy, Philadelphia, said that he does not agree with Dr. Camp in describing this condition as a purely muscular disease. While the theory, of course, of inelasticity of the muscles will hold good in certain directions, yet there are certain nervous manifestations which, he thinks, can not be explained by the condition of the muscles. The loss of elasticity, of course, will explain a decrease, but the reflexes are often increased, and it will not explain the tremor. It does not explain the sensory and trophic disturbances so often noted. The changes in the nervous system bear a more intimate relation to the disease than the changes in the muscles. In reference to Dr. Camp's statement that the disease is not one

which occurs in the young, Dr. McCarthy recalled a case in which paralysis agitans developed before the patient, a man, was 30 years of age. The individual had worked in lead for many years from boyhood, and before the development of the disease he had extensive arteriosclerosis.

Dr. C. D. Camp, Philadelphia, said that the anatomic basis of the muscular rigidity and the tremor in paralysis agitans is in the muscles, as against this Dr. McCarthy has mentioned exaggeration of the knee jerks, but most observers are agreed that the knee jerks are generally normal in this affection. There is no reason why the same influence or toxin that produces the degenerative change in the muscles should not also produce secretory and other similar symptoms. The origin of this toxin is not known, but Dr. Camp called attention to the evidence which seems to connect it with the parathyroid glands, and to the very suggestive changes in the parathyroid glands found in his cases. The pathologic conditions in the central nervous system are the changes of senility; they are not constant in paralysis agitans, and they are found in old people who during life had none of the symptoms of paralysis agitans. It is generally agreed that the tremor in the disease is caused by some lesion in the neuromuscular mechanism that regulates muscle tone, but in sleep the muscles are relaxed and consequently the tremor stops. Muscle tone is increased on excitement, so is the tremor. It is evident that the cerebrum has a marked influence on muscle tone, but while such impulses probably originate there, the perversion which causes the tremor may be due to a lesion either in the spinal cord or in the muscles where they are received. There is no necessity for the perversion to occur at their origin, in order to act normally the impulses must be normally transmitted and received, but a lesion in the internal capsule by completely stopping all impulses naturally stops the tremor. This explains those cases in which a tremor affected all four extremities, but after the occurrence of the hemiplegia the tremor stopped on the paralyzed side.

ACUTE OTITIS MEDIA.*

W. J. LEACH, M.D.

Lecturer on Diseases of the Eye, Ear, Nose and Throat and on Physiology, Kentucky University Medical Department.

NEW ALBANY, IND.

The various forms of otitis media depend not only on their varied etiology but also on their management and treatment. They depend also on the systemic condition of the patient as well as on the duration of the disease.

ETIOLOGY

A few cases are the result of direct injury, but the greatest number are the result of a specific infection, and are usually secondary to some nasal or pharyngeal disease, such as catarrh, adenoids or Eustachian tube disease, which is usually secondary to nose or throat disease. Nasal obstruction is an extremely frequent cause of otitis media, because it interferes with the ventilation of the Eustachian tube, and stenosis of the tube means an inability of the middle ear to drain itself. By this means various bacteria, pathogenic and otherwise, gain entrance into the middle ear and set up an inflammation. Chilling of the body and ill advised baths, as river bathing out of season, is also a frequent cause of otitis media.

But besides the Eustachian tube there are two other ways by which bacteria may gain entrance to the tympanic cavity, namely, by the external canal through a perforated drum, and by way of the blood and lymph stream. The latter, however, is very rare, but sometimes occurs in syphilis. We assume and believe that every case of otitis media is the result of a bacterium of some

103 *Deutsch. Ztschr. f. Nervenheilk.*, 1904.

104 *Med. News*, Dec. 2, 1905.

* Read before the Floyd County Medical Society.

kind Bacteria may be found in any and all throats and noses, and yet if the Eustachian tube is healthy and properly performs its functions of ventilation and drainage, the middle ear is apt to escape injury, especially if there is no systemic disease to lower the local resistance. The systemic condition may influence the form of trouble as well as the progress and prognosis of the case.

Simple otitis media may result from any of the foregoing causes, and is known by the following pathologic conditions: swelling, redness, infiltration and exudation of the intra-tympanic mucous membrane and patches of broken down epithelium. The bony wall also partakes of this pathologic state. The exudate contains mucous, blood and sometimes pus and various bacteria and varies in color accordingly.

SYMPTOMS AND COURSE.

The important symptoms are paroxysmal pulsating pain in ear and face, worse toward evening, in children often accompanied by high fever, delirium and convulsions. On examination with the speculum or, what is better, Seigle's otoscope, we find the drum is red and bulging, if it is not badly retracted from former diseases. Especially is this true of its postero-superior-quadrant. As a rule, all the landmarks are obliterated except the short process which appears as a yellow spot. The hearing is rapidly impaired.

If the case runs a favorable course the pain and redness of the drum grow gradually less in three or four days, though the hearing may be unimproved, but recovery takes place in about four weeks. This condition is distinguished from myringitis by the greater impairment of hearing and increased tympanic distension. If it runs an unfavorable course it may last indefinitely.

TREATMENT

In the acute simple otitis media this consists of alleviating the pain and treating the nose and throat with cleansing antiphlogistic agents, to facilitate drainage and ventilation to the tympanum by the Eustachian tube as soon as possible. The pain is best relieved by instilling within the external canal a 4 per cent solution of cocain, preceding it with a douche of hot boric acid solution, having the patient lie on the opposite side to the one affected, and then applying heat and repeating the douche and cocain frequently if necessary. If the bulging of the drum and the pain increases after thirty-six hours treatment, then do a myringotomy and drain thoroughly, making the incision in the most dependent part of the bulged portion of the drum, which will usually be found in the postero-inferior-quadrant. Myringotomy can be done without pain after the instillation of a 10 per cent solution of cocain with a 1-1,000 solution of adrenalin. If the drum is not incised it will finally rupture and slough with ragged edges and frequently does not close, leaving the ear exposed to the constant danger of infection. By relieving the intra-tympanic pressure and tension of the membrane by means of the incision the nutrition and reparative power of the drum are preserved, and, as any clean-cut wound will heal more quickly and surely than one made by sloughing, we shall, therefore, lessen the danger of permanent perforation. But more important than all, by early incision we lessen the danger of bacterial invasion of the mastoid cells with its consequent mastoiditis. The cavity should be evacuated and good drainage kept by aspiration and by douching with warm antiseptics.

Hydrogen peroxid may be used as a cleansing agent and the ear mopped out with dry cotton until it is perfectly clean, then with a hand powder-blower fill the canal one-third full of boric acid and insert cotton. This treatment and dressing should be performed by the doctor or nurse, otherwise it is poorly done. When the discharge has ceased use 10 per cent ichthyol in liquid petrolatum instead of the powder and continue until the drum is healed, during which time the nose and throat must be constantly treated. We now begin with special measures to restore hearing, then after each nasopharyngeal treatment we practice Politzerization, which has for its special object free ventilation of the tympanic cavity. Do not depend on the family for any part of the treatment, if you do you will fail. If tympanic ventilation is interfered with by stenosis of the Eustachian tube it must be opened or closing of the drum will not take place, and then we must remove any and all naso-pharyngeal obstructions, such as adenoids, enlarged tonsils, septal spurs, enlarged turbinates, polypi, deviated septum, etc. If there is simply a Eustachian salpingitis we may have to resort to bougies. As these naso-pharyngeal abnormalities are the greatest cause of tympanic disease, as well as of many other troubles, it is far more expedient to remove them than to wait and only partially succeed in restoring the middle ear after it has been disturbed by these abnormalities. Every pathologic pharyngeal condition promptly treated as it arises will greatly reduce chronic middle-ear disease.

PROGNOSIS

In simple acute otitis media the prognosis is good if the trouble is properly treated early and continuously. If it is neglected for two or three weeks it goes on to perforation, partial destruction of the middle ear, and may merge into chronicity. This, if it occurs, is troublesome to deal with and often involves the mastoid. In neglected perforative otitis media, which is apt to involve the accessory cavities and mastoid cells, we have a disease which is most serious, and yet parents, and sometimes physicians, will say, "Oh, the child will outgrow it, and you can't treat it successfully anyway." Why not say the child will outgrow a broken leg or a depressed skull or a cleft palate. It is nearly as rational. It is a formidable and difficult disease with which to deal, and owing to its intra-osseous location it becomes necessary to be persistent and aggressive and sometimes radical in its treatment, and often mastoidotomy is a conservative instead of a radical mode of treatment.

In cases of acute purulent otitis media and mastoiditis what are the purposes of opening the mastoid? First, to promote better drainage, second, to limit the extension of the infection, third, to remove necrosed bone and promote early healing. The indications for opening the mastoid in acute mastoiditis are: First, tenderness over the antrum, persisting for three days, after freely incising Shrapnell's membrane. Second, if the discharge from the ear suddenly grows much less while other symptoms remain, with an elevation of temperature, chills and sweats, denoting the opening up of the new channels and fields of infection. Third, a flow of pus too great to have been produced by so small a cavity as the tympanum, indicating invasion of the cells. Fourth, many surgeons regard a bulging of the postero-superior wall of the canal as a positive sign of mastoid disease and indicating interference, a few say it sometimes occurs with simple otitis media.

It seems rational to make it a rule to at least drain and remove necrosed bone in every case of true purulent mastoiditis, and although many cases recover without interference, it is certainly a long tedious and dangerous route. To say the least, such patients should be under the immediate attention of a surgeon until recovery is complete. Like appendicitis, its progress is insidious and its ravages hidden to an ordinary observer, until the mastoid has been explored and if mastoid surgery fails, it is usually because it has been postponed too long or the exploration has not been thorough and some foci of infection have not been found. The way to success in otology is to never let an acute otitis become chronic.

As the general practitioner is apt to see the case first it behooves him to be vigilant and prompt in treatment and advice, so that no time be lost, for the earlier pathologic condition is much more amenable to treatment and yields a more pronounced success, while neglected cases last a long time and have an uncertain outcome.

DIFFERENCES IN THE PHYSIOLOGIC ACTION OF THE SALTS OF AN ALKALOID *

ORVILLE HARRY BROWN, Ph.D., MD

Assistant Professor of Pharmacology Marion Sims-Beaumont
Medical College.
ST. LOUIS

Whether or not all the salts of an alkaloid, when the differences in their solubilities are excluded, have the same physiologic action is a question which is usually evaded in text-books on pharmacology and therapeutics. It is the general opinion that all the salts of an alkaloid, in the doses in which they are ordinarily administered, do have, aside from the local effect due to differences in solubility, the same action. Cushny,¹ speaking of the excessively bitter taste of quinin, says that it may be prescribed as a salt of tannic acid. This salt is exceedingly insoluble and is consequently almost tasteless. The pure alkaloid may be advantageously used for the same purpose and for the same reason. Where a rapid action is desired, a freely soluble salt—as the hydrochlorid, the bisulphate or the hydrobromate—is usually employed. Such salts as the above are the ones which are usually chosen for hypodermic administration. The only questions considered are whether it is sufficiently soluble and whether it is non-irritating.

Such statements are a fair example of the ordinary text-book descriptions of the different actions and indications for the use of the various salts of an alkaloid. It is not uncommon, though, for a physician to use one salt of an alkaloid to the exclusion of all others, because he believes he gets better results with it, while another doctor may be of the same opinion regarding a different salt of the same alkaloid. One point which the average physician may tend to ignore is that when a definite quantity of the salt of an alkaloid is given, unequal amounts of the alkaloid are administered. For example, when one-sixtieth of a grain of strychnin hydrochlorid is administered, more of the pure alkaloidal strychnin is given than when a sixtieth of a grain of strychnin salicylate is dispensed.

I have long been of the opinion that it is probable, especially with those alkaloids which are administered in considerable quantities, that there are different quan-

tative effects depending on the acid with which the alkaloid is combined

Apropos of some work² which I was doing with Nielson on the effects of various salt solutions on enzymatic and catalytic action, the various obtainable salts³ of strychnin and caffen were also tried in the same way. In tables Nos 1, 2 and 3 are given the results of a list of sodium, of strychnin and of caffen salts, respectively, on the splitting of hydrogen dioxide by a watery extract of kidney or pancreas. These tables are introduced for the sake of making a comparison of these results with those which are given in the experimental portion of the paper.

1 Cushny. Text book of Pharmacology and Therapeutics 3d edition p. 368

2 Nielson and Brown. Am Jour of Phrs., vol xii, 1904 p 374.
3 Brown and Nielson. Ibid., vol xiii, 1905 p 427

METHODS

The easily obtainable salts of the alkaloids morphin, strychnin and quinin were used. The solutions were made in fractional normal concentrations. By this method a solution of every salt of an alkaloid, of a certain designated concentration has the same amount of the free alkaloid as a solution of the same concentration of every other salt of the same alkaloid. For illustration, a N/1000 solution of quinin sulphate contains the same amount of the alkaloid as an N/1000 solution of quinin valerianate, notwithstanding the inequality in the molecular weights of sulphuric acid and valeric acid. The calculations of the molecular weights were made from the formulas given in Merck's (1902) Index.

The solutions were tested on paramecia. These animals were selected because they could be obtained in a reasonably pure solution. They are skimmed from the top of the solution in which they have been growing and are placed in a vessel with its greatest dimension in the vertical direction. Preferably a small-mouthed flask is used. The organisms are thus obtained in considerable numbers in a single drop from the upper layers of the solution in this vessel. In this way other organic material in the liquid was allowed to settle to the bottom and be separated from the paramecia. The organisms are of such a size that they are easily seen under the lower power of a microscope, and, since when alive they are always moving, their ceasing to move is a reliable index of the toxic effects of the solution. A simple unicellular organism of this sort gives more accurate results than a more complex organism would, as the possibility of chemical reactions of the alkaloid with elements of the organism are less likely to occur.

Into a flatbottomed saltcellar of about 10 c.c. capacity were placed 5 c.c. of the solution to be tested. The vessel was then placed on the stage of a microscope under a low power. One, two or three drops of the paramecia, depending on the number of organisms in a drop, were then put into the solution, which was instantly stirred. The exact time of the introduction of the drop of paramecia into the solution was noted.

It was easy to see through the microscope when the death of the organisms occurred. The testing of all the solutions in one concentration was carried out with the conditions constant throughout. The paramecia were taken from the same culture, the same number of drops were put into each solution, and each test was performed the same day and as nearly at the same hour of the day as was possible. In the instances where the drug did not act too rapidly each member of a series of tests was carried out at the same time.

EXPERIMENTAL RESULTS

The results obtained in the various tests are indicated by tables Nos. 4, 5 and 6, the data of which were selected from the results of the numerous experiments performed.

Table 4 shows that paramecia are not very susceptible to the solutions of morphin salts. An exposure of 24 hours to the salts, however, suffice to kill the major portion of the organisms in any one of the solutions, except that of morphin acetate. There is noticed that during the first two hours' exposure of the organisms to the solutions many more have perished in one solution than in another. The toxicity of the morphin salts in solution in N/100 concentration increase as follows:

The least toxic is the acetate, followed by the valerianate, ferrocyanid, tartrate, bromid, sulphate, phthalate and meconate, in the order named. By reference to the

table the exact relation of one solution to the other can be discerned.

TABLE 4

Solutions and Concentrations Used	Percentage of Paramecia Dead				
	2 hrs.	3 hrs.	7 hrs.	12 hrs.	24 hrs.
n/100 morphin acetate	0	2	5	5	5
n/100 morphin valerianate	5	40	90	98	100
n/100 morphin ferrocyanate	5	60	90	100	100
n/100 morphin tartrate	10	80	95	100	100
n/100 morphin bromid	20	40	60	95	100
n/100 morphin sulphate	60	90	98	100	100
n/100 morphin phthalate	80	95	99	100	100
n/100 morphin meconate	90	95	99	99	100

Table 5 presents some striking results. Paramecia were killed almost instantly when they were put into a solution of an N/50 concentration of strychnin valerianate, but lived for a period of twelve minutes in the same concentration of a solution of strychnin hyposulphite. The other salts of this alkaloid in solutions of the same concentration, when their relative toxicity for paramecia is considered, fall in between the two mentioned. A reference to the table reveals the position of each salt. In the N/100 concentration, the salts remain in the same order, and the only variations noted are that each requires a little longer time to produce the death of the organism. Strychnin iodide in N/200 concentration is fatal to the paramecia in three minutes, while strychnin salicylate, in the same concentration, is fatal in seventy seconds.

TABLE 5

Solutions Used.	Number of Seconds Paramecia Lived in Concentration of	
	N/50	N/100
Strychnin valerianate	5 sec.	
Strychnin acetate	5 sec.	30 sec.
Strychnin nitrate	45 sec.	60 sec.
Strychnin chlorid	65 sec.	80 sec.
Strychnin sulphate	70 sec.	120 sec.
Strychnin bromid	75 sec.	150 sec.
Strychnin arsenate	90 sec.	300 sec.
Strychnin glycerophosphate	110 sec.	480 sec.
Strychnin phosphate	140 sec.	900 sec.
Strychnin citrate	180 sec.	1200 sec.
Strychnin hypophosphite	720 sec.	

Table 6 shows there is a wide variation in the toxicity of certain quinin salts, as, for instance, the salicylate and the dibromid. The former acts twenty-four and a half times (figures taken from column No. 3) as rapidly as the latter. The other salts experimented with fall in between these two extremes. The first, second and fourth columns, each representing experiments with paramecia from different cultures and at different times, show slight variations in the relative toxicity of certain salts, but there are no very wide discrepancies.

The changes induced in the paramecia by the alkaloidal salts are characteristic. The organisms which normally are oblong, soon after being put into the solution of a rapidly acting chemical, become nearly round or spherical. The protoplasm becomes coarsely granular and its refractive power for light is consequently increased in some places and decreased in others. This change simulates very closely the one produced in the same organisms when they are deprived of oxygen, as observed by Loeb and Hardesty,⁴ and Budgett.⁵ These

⁴ Loeb and Hardesty. *Archiv f. d. ges. Physiol.*, [ix] 1895, p. 553.

⁵ Budgett. *Am. Jour. of Phys.* vol. 1, 1898, p. 210.

changes come on quickly or slowly after introduction of the paramecia into the solutions, depending on whether the chemical killed the animalcule quickly or after a considerable period

TABLE 6

Solutions Used	Time Paramecia Lived in Concentrations			
	N/100 Sec	N/200 Sec	N/1000 Min	N/1000 Min
Quinin salicylate			8	
Quinin citrate			9	
Quinin valerianate	10	10	14	2
Quinin sulphate		30	16	1
Quinin ferrocyanid			16	
Quinin iodid	30	45	19	2 5
Quinin lactate	30	57	20	4
Quinin phosphate		80	20	10
Quinin acetate		80	22	2
Quinin chlorid	30	80	23	2
Quinin bromid	15	10	23	2
Quinin hypophosphite	30	15	24	8
Quinin arsenate		45	25	1
Quinin sulphochlorid	120	180	82	23
Quinin dichlorid	10	10	87	30
Quinin ditartrate		450	97	32
Quinin sulphophenylate	150	540	105	82
Quinin disulphate	120	530	125	25
Quinin dibromid		120	190	33

It was a rather interesting fact that the paramecia of the same cultures and of different cultures varied considerably in their degree of susceptibility to any one solution. This is shown by the third and fourth columns of Table 6. In one instance an N/1000 solution of quinin sulphate killed the organisms in one minute, while in the case of paramecia from another culture sixteen minutes were required to destroy them.

The variations noted among the individuals of one culture were especially marked in case of those solutions which required a considerable period to produce their complete toxic effects. In those solutions which acted rapidly the variations in susceptibility of the organisms were scarcely noticed at all. For this reason those alkaloids whose salts were usually very soluble were used in fairly concentrated solutions. Many of the salts of quinin, however, are only slightly soluble.

EXPLANATION AND DISCUSSION OF THE RESULTS

On first thought it might seem possible that the results are due to an error in making up the solutions, since such very small amounts of an alkaloid exist in a few c.c. of even the more concentrated solutions used. The solutions were all made, however with great care. The fact that there are much wider variations in toxicity between solutions of two salts of the same concentration than there are between two widely different concentrations of one alkaloidal salt is conclusive evidence that the results are in no great measure due to any error in the making up of the solutions. For example, a N/100 solution of strychnin acetate is fatal to the paramecia in five seconds, while a N/100 solution of strychnin citrate kills the organisms in three minutes and a N/200 solution of strychnin acetate requires only thirty seconds to produce the death of the organism. The latter solution contains just half the amount of the pure alkaloid in either of the two former and yet it kills the paramecia in one-sixth the time required by the strychnin citrate.

This is also noticed with many of the other solutions. That the reaction of the solutions is not accountable for the result was shown in the case of the quinin salts, where very careful tests of the reaction were made. Solutions of the other alkaloidal salts are practically neutral. The double salts of quinin are neutral, and

yet considerable variation in the action of these salts is found. Most of the other salts of quinin are very slightly alkaline, and each has practically the same amount of alkalinity. Distinct variations in the toxicity of these salts is also observed. It is an interesting fact that the double salts of quinin are less toxic for paramecia than the others. This is noticed by referring to Table 6.

By a comparison of Tables 1 to 6, inclusive, some interesting relationships are revealed. For instance, sodium valerianate stimulates the splitting of hydrogen dioxide into water and oxygen by kidney extract very markedly, strychnin valerianate also has a decidedly accelerating action on the hydrolysis. None of the caffeine salts increase the amount of oxygen given off from the peroxid of hydrogen but caffeine valerianate allows more than any other salt. The valerianates of quinin and strychnin are the most toxic of the salts of these alkaloids for paramecia. The acetate is found in each instance close to the valerianate. Strange to say, the valerianate and acetate of morphin, instead of being the most toxic of any of the salts, as is the case with strychnin and quinin, are the least toxic of the salts employed. The citrate stands close to the acetate and valerianate in every case except the strychnin citrate when used on paramecia. In this instance, instead of being very toxic, as would be inferred from its effects on the catalysis it is one of the least toxic of the strychnin salts. The citrate of morphin was not worked with. Very likely other analogies would have occurred had the salts of the same acids been used in each instance. Further experiments must be done along this line with an idea of the comparisons.

SUMMARY AND CONCLUSIONS

The acid with which certain alkaloids, strychnin, quinin and morphin, are combined alter decidedly the pharmacologic action of the alkaloid—at least in regard to their toxicity for paramecia.

The most toxic salts of strychnin and quinin are in some instances at least those which stimulate catalytic processes the most markedly. The salts of morphin with the smallest degree of toxicity in some instances at least, are the salts of those acids, the sodium salts of which stimulate the catalysis the most markedly.

NOSTRUMS AND PROPRIETARIES VS U S PHARMACOPEIA AND NATIONAL FORMULARY PREPARATIONS *

HENRY P. HYNSON, PH G
BALTIMORE

The title assigned to this article implies a contest or a trying, not, as I understand it, a test of the relative merits or values of the several classes of medicines, enumerated from a pharmacologic, pharmaceutical or even a therapeutic standpoint, but a test of their respective merits or values rated by their effects on the progress, utility and characters of medicines and pharmacy.

That proprietary medicines some of them veritable nostrums are in active competition with regularly authorized and open formula preparations for the patronage of physicians is abundantly proven by the oft appearing detail man by the prodigious amount of mail received by physicians and by the teeming advertising pages of medical journals.

* Read at a joint meeting of the Section on Clinical Medicine and Surgery of the Baltimore City Medical Society and the more Branch of the American Pharmaceutical Assoc. at more Nov 16 1906.

That these same proprietary and often times secret formula preparations have already won considerable favor with physicians is unmistakably shown by the figures presented here to-night, by frequently appearing statistics of a similar character and by the personal knowledge of all concerned

USE OF PROPRIETARIES BY PHYSICIANS

The use of proprietaries by physicians is not altogether new, fifty or sixty years ago it had hardly begun, but its gradual, rather rapid increase is shown by the results obtained from an examination of 1,000 prescriptions in 1859, 1,000 in 1879 and the same numbers in 1899 and 1905, respectively. The percentages of proprietaries presented in these different periods were, in order, 1 per cent (1 in 1,000), 8 per cent, 18 per cent and 21 per cent. As tabulated, these figures represent such products only as have no really legitimate excuse for existing and do not include prescriptions for definite chemicals, although such may have had restricted ownership. The figures may be advantageously used as a means of comparison, because, fortunately, they were compiled, consistently, by one person and because they came from the same location, where were the same class of physicians and patients throughout all the different periods, periods previous to the agitation, lately prevailing and still active. An examination of two series of 500 consecutive prescriptions showed 21 per cent of proprietaries in 1905 and 18 per cent in 1906, a decrease of 3 per cent. It seems only fair to state that in these 18 prescriptions in a hundred, proprietaries did not always appear alone, but in a large number of cases were in combination or were used as vehicles (elixir of lactopeptin and Fairchild's essence of pepsin with other proprietaries of the same nature taking the lead). The frequent use of proprietaries, as vehicles, pure and simple, is significant and should make its impress on those in charge of the revision of the Pharmacopeia and the Formulary.

The reliability and consistent relationship of these figures is interestingly confirmed by an examination of the same numbers of consecutive prescriptions written in 1904 on the files of another store, located several blocks away, where different customers and many different physicians were concerned. Here, it appears, about the same percentage of proprietaries was used, 19 per cent, and about the same conditions regarding combinations and vehicles prevailed, but the percentage of physicians not using proprietaries, at all, was larger, 72 per cent, as compared with 57 per cent and 64 per cent, respectively in 1905 and 1906 at the other pharmacy. It may be interesting to learn that 125, 115 and 107 were the respective numbers of different physicians writing the several series of 500 each.

OBJECTIONS TO PROPRIETARIES

At this point it may be very properly asked. What are the real objections to proprietaries, secret formula products after all? There is really no great objection to them *per se*, if no better knowledge of medicines than is had of them is required, or if something better is not desired. Indirectly, however, they are very objectionable, possibly most objectionable because they are, verily, in direct opposition to the liberal and benevolent principles on which true medicine and true pharmacy are based because they are in direct opposition to real science and to truth itself, making whatever error that follows such objections a natural consequence, their use encourages or falsely rewards pretense and makes a

market for wrongly or dishonestly appropriated current knowledge, their use affords no encouragement to true and advanced pharmacologic and therapeutic attainments and certainly makes impossible that often very desirable and special adjusting of remedy and dosage, that is reasonably consistent with the extremely precise methods employed in all other departments of medical and surgical practice.

The development of science has, as is well known, in a number of instances, proven the worth or falsity of prevailing empiric practices, and so the very latest developments may prove, with startling exactness, just why some private empirical compounds have been efficacious in many cases and strangely disastrous in others. This, it is ventured, will be found due to the presence of the supposedly secondary and what has heretofore been considered a mere pharmaceutical agent, which in Pharmacopeia and National Formulary preparations is known and may be reckoned with. But who will be able to estimate the action of the hidden agent in proprietaries, which often times is the very "trick" on which depends their commercial value. It is open to every physician to know that ammonium acetate in large excess and ammonium chlorid in considerable quantity are constituents of the well-known Basham's mixture. And who is prepared to say just now that the effect of ammonium chlorid on blood coagulation is entirely different from the effect of calcium chlorid? Yet, certain we are that ammonium chlorid is present. Few physicians, however, know that the most popular proprietaries, supposed to contain a combination of peptone or albumin with iron and manganese, also contain large quantities of citrates, quantities often much in excess of an amount actually needed to keep the so-called peptonate of iron in solution. The citrate, either of ammonium, potassium or sodium, is used, the agency of either one of these is necessary to preserve the combination of iron and peptone in solution and, seemingly, the smallest quantity of sodium citrate that is efficient is not less than 7.5 grains per fluid ounce. When it is remembered that much larger quantities are used in some of these proprietaries and that an ounce is directed to be taken at a dose, it can be readily seen that the effects of these alkaline citrates must be thought of, especially in view of their effect on blood coagulation. It may be further stated that when these citrates are not used, hydrochloric acid is employed and necessarily breaks up the organic combination and forms a simple solution of iron chlorid, mixed with a solution of peptone. The official elixir of iron, quinin and strychnin phosphates presents these agents as true phosphates held in solution by the presence of the secondary or pharmaceutical agents, sodium citrate and ammonium acetate but no medical man has been informed that some of the private formulas, for proprietary elixirs of the phosphate of iron, quinin and strychnin produce, as has been repeatedly proven, elixirs of the chlorids of these substances. The National Formulary elixir of pepsin, bismuth and strychnin presents these remedies in the logical, slightly acid form, while the examination of private formula, proprietary elixirs of this kind often discloses the fact that the bismuth is held in solution through an excess of alkali at the expense of pepsin and with the possibility of it precipitating the alkaloid strychnin.

Recent publications by the Council on Pharmacy and Chemistry of the American Medical Association make confirmatory and often times surprising revelations and it appears that even though a manufacturer of unfor-

tunate compounds may by intention be honest he is frequently mistaken, badly mistaken, not only in the pharmacology of his product but in its chemistry as well, as these same publications, to be charitable, make it plain that many of the proprietaries offered must be both owned and promoted by the veriest laymen, since these in their unfortunate and unbecoming ignorance use strictly chemical terms and graphic chemical formulas to describe a simple mixture "Horrible examples" of the personnel of proprietary ownership and exploitation would be a show that would, in misfits and *mc-alliances*, rival "the greatest on earth"

Uncertainty, unreliability, pretended originality and false claims of unusual potentiality are the really hurtful, harmful objections to these proprietary medicines which, because of these very characteristics, become veritable nostrums. The objections, from an ethical or professional point of view, so well known to all of us, while not, perhaps, directly destructive, are far reaching in their retarding effects on the advancement of pharmaceutical practice and on the integrity of pharmacists. Few men among us seem able to resist their seductive influences which so often tend and lead toward quackery.

I have in my possession two advertisements directed to the laity in lay publications, one that of a New York pharmacist of unusual scientific attainment and at one time the chief exponent of ethical pharmacy in the metropolis, the other that of a Baltimorean, a former retail pharmacist. Both take their products, originally presented to physicians for their sole use, directly to the laity and claim for their products the endorsement and patronage of physicians. Apparently, forgetting there ever existed anything like ethics and yet, knowing them as I do, I believe they were perfectly sincere and honest when they first presented their products to the medical profession. I believe the promoters of the hybrid-named, antagonist to pain proprietary which has now become a "family remedy" advertised to the laity were as sincere and as honest in the beginning. None of these would have been tempted by Pharmacopeia preparations, none could have gone to the laity with National Formulary products, and yet those demoralizing products are not one whit better than these.

The unfortunate, detracting associations which these proprietaries and many times nostrums make for medicine and medical men, are neither edifying nor helpful. Look in the display windows or over the advertising lists of dealers in quack remedies and "patent medicines" and you will be unable to differentiate between the rankest of these and the proprietaries, regularly prescribed by many of our most reputable physicians. Your "favorite" proprietary prescription is often seen standing close beside Dr. Pierce's Favorite Prescription, with old mother Pinkham and Peruna's handsome belle doing the honors to both with equal deference. It is not in such company, it is our proud pleasure to note, that we find chaste and fair maidens, the inevitable offspring of our most creditable national standards.

IGNORANCE, INDOLENCE AND LUST

While regarding medicine with reverent respect, may it not be said that even it suffers much from such associations and may it not appear that because the mother's or mistress' skirts have been touched at all the daughter's or the handmaidens may have become sensibly soiled. The most hopeful moralist must be he who, in his philosophy, reduces the initial causes of evil to the smallest possible number. And he who believes all can be

traced to three, ignorance, indolence and lust, sees promise in the possibility of lessening any of the three.

In this instance it may be polite to modify the terms and say that it was ambition, not lust, that has led all sorts and conditions of men to present to physicians for their patronage the multitude of proprietaries and nostrums now afflicting us, that it was want of thought and lack of special training, not ignorance, that made it possible for the exploiter to have his extravagant claims accepted and his impossible promises credited, that it was the physician's lack of time and love for facility, not indolence, that has led him to use ready-made and easily ordered proprietaries.

And on this same occasion and for the same polite reason it may be well to say that it was want of interest and lack of opportunity to equip himself, not ignorance, that prevented the average pharmacist from being able to impress physicians with his ability to meet their pharmaceutical needs in an up-to-date manner and equal to the promoter of proprietaries, it was love of ease and fear of exhaustion, not indolence, that has kept the pharmacist from selling official and semi-official products in competition with proprietaries.

It matters but little under what head of human weakness we may classify the causes already enumerated, in any event, they must be charged to individual shortcomings, from a higher viewpoint, inexcusable and as requiring individual correction. There are, however, other causes for present conditions for which, it may be said, individuals are not responsible, but which must be laid at the doors of organization, association and education. An insufficient number of official, acceptable and efficient vehicles, the insufficient teaching of materia medica and pharmaceutical chemistry in medical schools, the sacrifice of true pharmaceutical discussions and demonstrations to purely commercial questions in pharmaceutical societies, the lack of a distinct understanding between the manufacturer and his legitimate distributor, the retailer, whereby the scope of each might be defined and the beneficial possibilities of each might be furthered, a lack of general and enthusiastic interest in the construction of the two standards, followed by a want of familiarity with their contents by all concerned, the slow revision and publication of the Pharmacopeia and the Formulary, the lack of frequent supplemental publications of corrections, improvements and additions. These are some of the causes with which we must reckon in our several guilds and institutions of learning.

In this land of the free and of great personal liberty we may not hope to accomplish so much as has been done in Europe by the hard hand of the law except from its educational power, but here it is from the kinder offices of affiliation and fraternity, of encouragement and helpfulness from the stronger to the weaker, that we must look for betterment and for final salvation.

Water Supply of Damascus.—The *Lancet* states that the water supply of the city of Damascus, Turkey, is very unsatisfactory. The city is provided with water from a distant source, which, before it arrives for distribution at Damascus, runs through plains valleys and villages and in its course becomes contaminated by many and various impurities. In the city itself, the water receives many new impurities in passing from house to house, and this explains the prevalence of typhoid in the city. It is now intended to alter the dangerous state of affairs. Water from the source will be provided and other general contamination impossible.

THE MODERN SURGEON HIS BENEFICENT AND EVER-EXPANDING WORK

SHELBY CHADWICK CARSON, A.M., M.D.
GREENSBORO, ALA.

I have selected the descriptive term "beneficent" not so much in contradistinction to a class of work that might be considered ill advised, rash or meddlesome nor as an insinuation that improper motives occasionally sway the actions of members of the profession, but because I have been impressed by the happy results of surgical intervention as a life-saving measure, while, on the other hand, I have witnessed the direst disaster following the failure to resort to it. The opinion prevalent among the laity that a surgeon delights in the opportunity "to cut and to slash," as they express it, is not justified by the facts.

The last ten years have wrought a considerable revolution in this respect, since the doctrine of conservatism has been extensively preached. One can judge how radical this change is by the tone of many of the prominent articles in the late periodicals and the transactions of well-recognized medical associations. Take, for instance, the discussion at the meeting of the American Gynecological Society, last May, by such well-known specialists as Baldy, Goffe and others on the subject, "Is Gynecology Dead?" whereas previously the suspicion of overdone work, if any existed, was directed to this particular field. Then the general surgeon was justly jealous of the encroachments on his domain by the gynecologist.

My many years of uninterrupted devotion to the profession have begotten an abiding faith in its high purposes and aims, so that any rare instance of unnecessary interference on the part of the surgeon I class as one of those unfortunate events incident to all great movements.

While each separate branch of medicine has its attractions, and, therefore, its votaries and its advocates, the science of surgery ranks second to none, if, indeed, it does not have priority over all cognate departments. Its results are usually so prompt and oftentimes even brilliant that it is highly gratifying to the earnest surgeon and eminently satisfactory to the patient. While the internist must often wait and hope for results, the surgeon strives and brings them to pass. The most marvelous transformations in the appearance and well-being of any individuals that I can now call to mind have occurred in those desperate "stomach cases," in which a wan, emaciated, miserable individual, apparently on the verge of dissolution, on the third day after a gastroenterostomy will have an expression of contentment and happiness that will do any one good to see.

Surgery is both a science and an art. Only a few weeks ago some writer said that probably this art had reached its zenith. About eight years ago I ventured the same opinion in a paper prepared for the Mississippi Valley Medical Association, saying "The art of surgery, the manipulative skill, the operative faculty, has probably reached its summit," but since then I have had the good fortune to see the leading surgeons in both Europe and America at work, and I feel sure they are even more adroit and expert than at the time I wrote. I have also had the opportunity of comparing two of our leading surgeons with themselves for two consecutive years, and I am convinced that there has been an improvement even in their operative skill.

But the science of surgery is practically without limit. Possibly the next decade may open up another avenue

of progress equal in importance to the period which evolved and almost perfected asepsis and antiseptics.

If any one accomplishment in surgery can be rated above another it is the ability to make a diagnosis both early and accurately. The importance of diagnosis can not be overestimated. So often, when a case is brought to him, the specialist is hampered by the advanced stage of the disease, owing to a failure on the part of some one to recognize the gravity of the situation. It should be the ambition of every physician to excel in this line, but this condition will be attained only by study and experience. The constant and habitual exercise of the sense of touch, especially as regards the internal organs—the dexterity in palpating and auscultating—should engage the earnest attention of all. One afternoon, in St. Peter's, I expressed to Hurry Fenwick my surprise at the readiness with which he made the diagnosis of diseased kidney. It was before the attention of the profession had been drawn so specifically to that region. His reply, "Why, only a little practice makes it easy," encouraged me to form a habit when going over a patient—even though I suspect nothing—to investigate carefully this particular organ merely to retain the "touch" that practice has enabled me to acquire. These early diagnoses do not simply redound to one's own credit and the good of the patient, but they greatly enhance the value of surgery generally. I am not prepared to go to such an extreme as to state that an exploratory incision for the sake of diagnosis is a reproach to a surgeon, because it is well known that even the most skilful can not tell exactly what he will find within the abdomen, but it is evident that each year makes it more akin to a reproach.

At first the surgeon had only a knowledge of gross anatomy, but finally this knowledge led "to the unfolding of minute anatomy and pathologic anatomy. On this foundation was erected the splendid structure of surgical pathology and bacteriology. Previous to this time surgery, like law, was taught and practiced largely by precedent. Surgical pathology and bacteriology transformed the old anatomic surgery. Along the line of pathologic physiology the next great advances in surgery will probably be made."

Surgical education in these days of progress is not complete without an extensive knowledge of practical pathology and surgical physiology as pertaining to glandular and lymphatic action. This fact is made more and more conspicuous in the principal clinics in the large centers. The simple fact that the small intestine carries only liquid stools and that the large bowel is the drying house, as it were, of the alimentary tract has already suggested some recent theories in the treatment of surgical diseases of the abdomen. Ochsner's brilliant results in appendicitis by keeping food out of the stomach and feeding by rectum led to special investigation and research by other observers and it was decided that when full or even partly filled the small bowel immediately begins its excursions to and fro within the abdominal cavity—its vermicular movements—and thereby scatters infection broadcast, that when empty it is quiet and, therefore, not an element of danger. Surgery quickly takes advantage of this in that after an operation it advises covering the field carefully with omentum as a protection against the migratory movement of the small intestines, or to utilize some fixed portion of the large bowel—the sigmoid for instance—as a safeguard by placing it against the stump or field of operation. It is well when operating in the abdomen to take into consideration the facts that "granular mat-

ter and coarse débris are absorbed only through the lymph spaces at the diaphragm, while the fluids are rapidly absorbed by the peritoneum, that there are three cavities of the peritoneum to be drained, viz the right and left flanks separated from each other by the spinal column and the pelvis separated from the flanks by the psoas muscle. Either flank holds more fluid and is an inch deeper than the pelvis. The body must be elevated to an angle of sixty or seventy degrees to drain properly by Fowler's position. The entire cavity can be drained by gravity by a lateral position."

The surgeon is forced to a thorough study and appreciation of the lymphatic system and the manner that infection travels through the glands. One of the most practical discourses along this line that I ever heard was from a surgeon of note while he was engaged in extirpating a large thyroid in a case of exophthalmic goiter.

In July I witnessed the fifty-second operation for goiter—probably one-half of them of the exophthalmic variety—that a noted surgeon had done since the beginning of the year. It seems that a nicety of discrimination is required as to the amount of thyroid tissue that is left.

There is another line of surgical work—as yet in the experimental stage—which in my opinion is of doubtful utility. It has some attractive as well as novel features. I refer to the transplantation of tissues as well as organs—a line of work now being prosecuted mainly by Garre, Payr and Pankow. A portion of a mother's thyroid has been successfully transplanted to the spleen of her child, and the kidney of a dog implanted into the neck of the same animal, while the renal artery has been united to the carotid, and the renal veins to the innominate veins without disturbing the renal function. Robert T. Morris has recently reported a successful case of ovarian grafting. Strange to say osseous grafts give very gratifying results, and it is not at all improbable that bone grafting will play an important rôle hereafter in the surgery of the extremities.

Page claimed that physical diagnosis is the "mathematics" of medicine, but when one undertakes to define surgery or even to confine it to certain limits there is but little common ground on which to agree. It is a less difficult task to enumerate some of the attributes of a surgeon which may prove germane to the subject. There are a few principles, however, that still hold good in this department, such for instance as "When in doubt, wait." The wisdom of this can scarcely be questioned when one has not the ready acumen to decide. Another is "Never operate unless confronted by an actual necessity." I would not take issue with this so long as it relates to major surgery. Minor operations are done every day when a positive necessity does not exist—under circumstances, for instance, as influence the comfort of the patient or for cosmetic effect. Again "Save every particle of tissue possible." In order to emphasize this principle Wyeth of New York while examining an injured hand in a clinic remarked in an exceedingly positive manner "Surgery does not carry with it the idea 'to lop off' but rather 'to build up'." The thought struck me then that that is a very happy expression but recently—since my mind has been engaged in the preparation of this paper—a negro woman came into my office, having traveled in a buggy about twenty-five miles and volunteered the information that she had a "lump of some kind as big as her fist that

hung from her privates." I at once thought of procidentia uteri or possibly an extruded uterine polyp, but imagine my surprise on finding an hypertrophied clitoris at least three inches in circumference at its origin, fully six inches long and ending in a bulbous-shaped mass about eight inches in circumference. This entirely concealed the vaginal orifice and shut in its secretions. The meatus urinarius was also beneath the mass. Consequently the odor was extremely disagreeable. As I threw a carbolyzed gauze around the tumor in order to examine it the better the thought went through my mind like a flash—if Wyeth were here now would he still say "Surgery does not carry with it the idea 'to lop off'?" It struck me that this thing certainly was sufficiently "built up." And thus it is when one attempts to lay down a rule for another in as broad a field as surgery.

By the most imperative demands the surgeon of late days is forced to make incursions into the field of obstetrics. And when it is wisely, skilfully and successfully done where else can the God-given power of man more pre-eminently manifest itself? I have never yet gained my consent to claim Cesarean section as entirely justifiable in placenta prævia and other anomalous conditions, but there is a rare dystocia in which Cesarean section offers the only avenue of escape for either the mother or the child. I have in mind now an antepartum hour-glass contraction in which a band of fibers, not Bandl's so-called ring, fully an inch in width, as firm as metal, encircled without compressing the child's neck at its juncture with the shoulders. No amount of anesthetic or efforts at manual dilatation would have any effect. Formerly in such cases the woman perished undelivered.

Whereas surgery, like law, was once taught by precedent, now a broader and ever broadening knowledge lifts one above the restrictions that pertain to mere work on gross anatomy, and gives more license—a license that will not be abused by the conscientious man—to the judgment of the individual operator. Surgeons are constantly having comparatively new problems to solve, facing rare conditions, for which there never has been a precedent, and what are they to do when so confronted? In my opinion, the conclusion of the whole matter is that a man of good judgment and discretion, possessing a sensitive conscience and governed by a high sense of moral rectitude, being thoroughly grounded in the present teachings of surgical science, has a right to blaze out a path for himself whenever the occasion arises. After all, in the final analysis the chief elements in good surgery are simplicity and common sense.

CLINICAL OBSERVATIONS ON BLOOD PRESSURE IN ARTERIOSCLEROSIS AND BRIGHT'S DISEASE

WITH SUGGESTIONS CONCERNING THE THERAPEUTIC CONTROL OF PERSISTENT HIGH BLOOD PRESSURE *

ARTHUR R. ELLIOTT, M.D.

Professor of Medicine, Post Graduate Medical School and Hospital, CHICAGO

The average systolic blood pressure is usually understood to be about 115 mm. of mercury when the estimation is made with a wide arm-band. It is practically impossible to fix an invariable standard for any physiologic phenomenon. In common with other physical processes, such as body temperature, respiration, urine excretion, etc., which are influenced by many conditions of every-

THE MODERN SURGEON HIS BENEFICENT AND EVER-EXPANDING WORK.

SHELBY CHADWICK CARSON, A.M., M.D.
GREENSBORO, ALA.

I have selected the descriptive term "beneficent" not so much in contradistinction to a class of work that might be considered ill advised, rash or meddlesome nor as an insinuation that improper motives occasionally sway the actions of members of the profession, but because I have been impressed by the happy results of surgical intervention as a life-saving measure, while, on the other hand, I have witnessed the direst disaster following the failure to resort to it. The opinion prevalent among the laity that a surgeon delights in the opportunity "to cut and to slash," as they express it, is not justified by the facts.

The last ten years have wrought a considerable revolution in this respect, since the doctrine of conservatism has been extensively preached. One can judge how radical this change is by the tone of many of the prominent articles in the late periodicals and the transactions of well-recognized medical associations. Take, for instance, the discussion at the meeting of the American Gynecological Society, last May, by such well-known specialists as Baldy, Goffe and others on the subject, "Gynecology Dead?" whereas previously the suspicion of work, if any existed, was directed to this particular field. Then the general surgeon was justly jealous of the encroachments on his domain by the gynecologist.

My many years of uninterrupted devotion to the profession have begotten an abiding faith in its high purposes and aims, so that any rare instance of unnecessary interference on the part of the surgeon I class as one of those unfortunate events incident to all great movements.

While each separate branch of medicine has its attractions, and, therefore, its votaries and its advocates, the science of surgery ranks second to none, if, indeed, it does not have priority over all cognate departments. Its results are usually so prompt and oftentimes even brilliant that it is highly gratifying to the earnest surgeon and eminently satisfactory to the patient. While the internist must often wait and hope for results, the surgeon strives and brings them to pass. The most marvelous transformations in the appearance and well-being of any individuals that I can now call to mind have occurred in those desperate "stomach cases," in which a wan, emaciated, miserable individual, apparently on the verge of dissolution, on the third day after a gastroenterostomy will have an expression of contentment and happiness that will do any one good to see.

Surgery is both a science and an art. Only a few weeks ago some writer said that probably this art had reached its zenith. About eight years ago I ventured the same opinion in a paper prepared for the Mississippi Valley Medical Association, saying "The art of surgery, the manipulative skill, the operative faculty, has probably reached its summit," but since then I have had the good fortune to see the leading surgeons in both Europe and America at work, and I feel sure they are even more adroit and expert than at the time I wrote. I have also had the opportunity of comparing two of our leading surgeons with themselves for two consecutive years, and I am convinced that there has been an improvement even in their operative skill.

But the science of surgery is practically without limit. Possibly the next decade may open up another avenue

of progress equal in importance to the period which evolved and almost perfected asepsis and antisepsis.

If any one accomplishment in surgery can be rated above another it is the ability to make a diagnosis both early and accurately. The importance of diagnosis can not be overestimated. So often, when a case is brought to him, the specialist is hampered by the advanced stage of the disease, owing to a failure on the part of some one to recognize the gravity of the situation. It should be the ambition of every physician to excel in this line, but this condition will be attained only by study and experience. The constant and habitual exercise of the sense of touch, especially as regards the internal organs—the dexterity in palpating and auscultating—should engage the earnest attention of all. One afternoon, in St. Peter's, I expressed to Harry Fenwick my surprise at the readiness with which he made the diagnosis of diseased kidney. It was before the attention of the profession had been drawn so specifically to that region. His reply, "Why, only a little practice makes it easy," encouraged me to form a habit when going over a patient—even though I suspect nothing—to investigate carefully this particular organ merely to retain the "touch" that practice has enabled me to acquire. These early diagnoses do not simply redound to one's own credit and the good of the patient, but they greatly enhance the value of surgery generally. I am not prepared to go to such an extreme as to state that an exploratory incision for the sake of diagnosis is a reproach to a surgeon, because it is well known that even the most skilful can not tell exactly what he will find within the abdomen, but it is evident that each year makes it more akin to a reproach.

At first the surgeon had only a knowledge of gross anatomy, but finally this knowledge led "to the unfolding of minute anatomy and pathologic anatomy. On this foundation was erected the splendid structure of surgical pathology and bacteriology. Previous to this time surgery, like law, was taught and practiced largely by precedent. Surgical pathology and bacteriology transformed the old anatomic surgery. Along the line of pathologic physiology the next great advances in surgery will probably be made."

Surgical education in these days of progress is not complete without an extensive knowledge of practical pathology and surgical physiology as pertaining to glandular and lymphatic action. This fact is made more and more conspicuous in the principal clinics in the large centers. The simple fact that the small intestine carries only liquid stools and that the large bowel is the drying house, as it were, of the alimentary tract has already suggested some recent theories in the treatment of surgical diseases of the abdomen. Ochsner's brilliant results in appendicitis by keeping food out of the stomach and feeding by rectum led to special investigation and research by other observers and it was decided that when full or even partly filled the small bowel immediately begins its excursions to and fro within the abdominal cavity—its vermicular movements—and thereby scatters infection broadcast, that when empty it is quiet and, therefore, not an element of danger. Surgery quickly takes advantage of this in that after an operation it advises covering the field carefully with omentum as a protection against the migratory movement of the small intestines, or to utilize some fixed portion of the large bowel—the sigmoid for instance—as a safeguard by placing it against the stump or field of operation. It is well when operating in the abdomen to take into consideration the facts that "granular mat-

ter and coarse débris are absorbed only through the lymph spaces at the diaphragm, while the fluids are rapidly absorbed by the peritoneum, that there are three cavities of the peritoneum to be drained, viz the right and left flanks separated from each other by the spinal column and the pelvis separated from the flanks by the psoas muscle. Either flank holds more fluid and is an inch deeper than the pelvis. The body must be elevated to an angle of sixty or seventy degrees to drain properly by Fowler's position. The entire cavity can be drained by gravity by a lateral position."

The surgeon is forced to a thorough study and appreciation of the lymphatic system and the manner that infection travels through the glands. One of the most practical discourses along this line that I ever heard was from a surgeon of note while he was engaged in extirpating a large thyroid in a case of exophthalmic goiter.

In July I witnessed the fifty-second operation for goiter—probably one-half of them of the exophthalmic variety—that a noted surgeon had done since the beginning of the year. It seems that a nicety of discrimination is required as to the amount of thyroid tissue that is left.

There is another line of surgical work—as yet in the experimental stage—which in my opinion is of doubtful utility. It has some attractive as well as novel features. I refer to the transplantation of tissues as well as organs—a line of work now being prosecuted mainly by Garre, Payr and Pankow. A portion of a mother's thyroid has been successfully transplanted to the spleen of her child, and the kidney of a dog implanted into the neck of the same animal, while the renal artery has been united to the carotid, and the renal veins to the innominate veins without disturbing the renal function. Robert T. Morris has recently reported a successful case of ovarian grafting. Strange to say osseous grafts give very gratifying results, and it is not at all improbable that bone grafting will play an important rôle hereafter in the surgery of the extremities.

Page claimed that physical diagnosis is the "mathematics" of medicine, but when one undertakes to define surgery or even to confine it to certain limits there is but little common ground on which to agree. It is a less difficult task to enumerate some of the attributes of a surgeon which may prove germane to the subject. There are a few principles, however, that still hold good in this department, such for instance as "When in doubt, wait." The wisdom of this can scarcely be questioned when one has not the ready acumen to decide. Another is "Never operate unless confronted by an actual necessity." I would not take issue with this so long as it relates to major surgery. Minor operations are done every day when a positive necessity does not exist—under circumstances for instance, as influence the comfort of the patient or for cosmetic effect. Again "Save every particle of tissue possible." In order to emphasize this principle Wyeth of New York while examining an injured hand in a clinic, remarked in an exceedingly positive manner "Surgery does not carry with it the idea 'to lop off' but rather 'to build up'." The thought struck me then that that is a very happy expression but recently—since my mind has been engaged in the preparation of this paper—a negro woman came into my office, having traveled in a buggy about twenty-five miles and volunteered the information that she had a "lump of some kind as big as her fist that

hung from her privates." I at once thought of procidentia uteri or possibly an extruded uterine polyp, but imagine my surprise on finding an hypertrophied clitoris at least three inches in circumference at its origin, fully six inches long and ending in a bulbous-shaped mass about eight inches in circumference. This entirely concealed the vaginal orifice and shut in its secretions. The meatus urinarius was also beneath the mass. Consequently the odor was extremely disagreeable. As I threw a carbolyzed gauze around the tumor in order to examine it the better the thought went through my mind like a flash—if Wyeth were here now would he still say "Surgery does not carry with it the idea 'to lop off'?" It struck me that this thing certainly was sufficiently "built up." And thus it is when one attempts to lay down a rule for another in as broad a field as surgery.

By the most imperative demands the surgeon of late days is forced to make incursions into the field of obstetrics. And when it is wisely, skilfully and successfully done where else can the God-given power of man more pre-eminently manifest itself? I have never yet gained my consent to claim Cesarean section as entirely justifiable in placenta prævia and other anomalous conditions, but there is a rare dystocia in which Cesarean section offers the only avenue of escape for either the mother or the child. I have in mind now an antepartum hour-glass contraction in which a band of fibers, not Bandl's so-called ring, fully an inch in width, as firm as metal, encircled without compressing the child's neck at its juncture with the shoulders. No amount of anesthetic or efforts at manual dilatation would have any effect. Formerly in such cases the woman perished undelivered.

Whereas surgery, like law, was once taught by precedent, now a broader and ever broadening knowledge lifts one above the restrictions that pertain to mere work on gross anatomy, and gives more license—a license that will not be abused by the conscientious man—to the judgment of the individual operator. Surgeons are constantly having comparatively new problems to solve, facing rare conditions, for which there never has been a precedent, and what are they to do when so confronted? In my opinion, the conclusion of the whole matter is that a man of good judgment and discretion, possessing a sensitive conscience and governed by a high sense of moral rectitude being thoroughly grounded in the present teachings of surgical science has a right to blaze out a path for himself whenever the occasion arises. After all, in the final analysis, the chief elements in good surgery are simplicity and common sense.

CLINICAL OBSERVATIONS ON BLOOD PRESSURE IN ARTERIOSCLEROSIS AND BRIGHT'S DISEASE

WITH SUGGESTIONS CONCERNING THE THERAPEUTIC CONTROL OF PERSISTENT HIGH BLOOD PRESSURE *

ARTHUR R. ELLIOTT, M.D.

Professor of Medicine Post Graduate Medical School and Hospital
CHICAGO

The average systolic blood pressure is usually understood to be about 115 mm. of mercury when the estimation is made with a wide arm-band. It is practically impossible to fix an invariable standard for any physiologic phenomenon. In common with other physical processes, such as body temperature, respiration, urine excretion, etc., which are influenced by many conditions of every-

* I read before the Chicago Medical Society Nov. 28, 1903.

day life, we find the degree of blood pressure likewise affected by a great variety of circumstances producing comparatively wide but transient fluctuations, especially in the direction of increase, so that it is almost impossible to speak of normal values for blood pressure. After making due allowance for these physiologic variations, experience would lead me to place the normal average limits of systolic blood pressure at from 105 mm to 140 mm. Any persistent elevation above the latter figure may be interpreted as constituting hypertension.

Essential hypertension is a condition, which, if once permanently established and pronounced, becomes a factor of great importance to the welfare of the individual, inasmuch as it entails a lasting increase in circulatory resistance, with consecutive structural changes in the heart wall and degenerative defects in the arteries themselves.

FIRST SERIES

The reports of blood pressure observations submitted herewith, concern only the variations in systolic blood pressure in certain cases of arteriosclerosis and chronic renal disease which have been under routine observations for considerable although variable periods of time. The blood pressure gauges used were Cook's modification of the Riva Rocci instrument with a 9 cm. arm-band, and the sphygmomanometer of Stanton. As nearly as possible exact conditions were duplicated at each application of the instrument. Physical repose and mental tranquillity were as far as possible secured. The great majority of the observations were taken with the patient in the sitting position, a comparatively few in the recumbent position.

I have had under observation during the past twelve months thirty cases of arteriosclerosis. Without exception these patients have sought relief from some functional or organic manifestation of the disease. Nine had prostatic hypertrophy, one cerebral thrombosis, one retinal hemorrhages, three choroiditis with visual defects, one angina pectoris, and a number have complained of dyspnea, precordial discomfort and cardiac irregularity.

In this series the average age was sixty-one years, and the average maximum systolic blood pressure 148 mm. In fourteen of the cases (47 per cent) the blood pressure fell within the normal range. Sixteen cases (53 per cent) displayed a systolic pressure persistently above the normal limit. Only six of the entire series (20 per cent) showed a blood pressure which could be called significant—a positive hypertension. In brief, these six cases are as follows:

CASE 1—Male, aged 81, has "pipe stem" arteries, dyspnea, chronic cough, cardiac hypertrophy, and a harsh basic systolic murmur. The blood pressure was invariably above 200 mm, and on one occasion 225 mm. The urine was rather scant and concentrated, and contained degenerative tube casts and albumin. I am not at all sure that the renal condition is not the cause of this man's hypertension.

CASE 2—Male aged 76, colored, spare individual, preacher, marked calcification of all superficial arteries. There is great dyspnea and slight malleolar edema. Urine has a few casts, no albumin, maximum systolic pressure observed, 175 mm.

CASE 3—Male, aged 41, spare, no syphilis, has attacks of anginoid character. General fibrosis of palpable arteries, with indications of aortic atheroma. Casts present, no albumin, maximum systolic blood pressure, 175 mm.

CASE 4—Female aged 70, nodular arteries, double senile cataract, chronic bronchitis, harsh basic cardiac murmur. Urine normal except for casts. Blood pressure 176 mm.

CASE 5—Male, aged 77, prostatic hypertrophy, harsh basal

systolic murmur, clanging aortic second sound, cardiac hypertrophy, no albuminuria, blood pressure 170 mm.

CASE 6—Male, aged 53, weight 131 pounds, syphilitic, fibrotic tortuous arteries, cardiac enlargement, basal systolic murmur, very reverberant second aortic sound, aortic dilatation, very dyspneic, no albuminuria, systolic blood pressure 200 mm.

The number of cases of arteriosclerosis included in the foregoing observations is not large, but the series has the distinct advantage of being made up of typical cases, each individual coming under treatment for some manifestation of arterial disease. A point of interest brought out by this investigation is the comparatively high percentage of cases (47 per cent) of arteriosclerosis, in which the blood pressure was below 140 mm, a normal limit which certainly can not be called excessive for a group of individuals averaging sixty-one years of age. This result is confirmatory of the observations of Carter, Potam, Groedel, Drieschfeld and others. It would appear that thickening and hardening of the superficial arteries on which we base the clinical diagnosis of arteriosclerosis does not constitute sufficient cause for development of high blood pressure. We are not to conclude because the radial, temporal and other palpable arteries are sclerosed that high tension necessarily exists. The sphygmomanometer is absolutely essential to clearing up this important point, and it should be invariably employed as a means of diagnosis in every case of arterial disease. It is practically impossible for the unaided finger, no matter how skilled the observer may be in pulse reading, to determine with accuracy how much of the hardness and firmness of an artery is produced by high pressure of the blood within the vessel, and how much is due to thickening of the arterial wall.

The paradoxical absence of cardiac hypertrophy in certain cases of well-marked and even advanced arteriosclerosis, is explained now that we realize that the essential element of high blood pressure may not be present in any given case, and that the degree of sclerosis of the superficial arteries is no reliable criterion, either of the severity of alterations in visceral blood vessels, or of the degree of tension present. It is clear that some underlying factor not accessible to our present methods of investigation must be responsible for the occurrence of high blood pressure in arteriosclerosis. What this determining cause is, we are not yet sufficiently advanced in the knowledge of our subject to say with certainty, although the researches of Hasenfeld and of Hirsch supply an interesting and probably correct explanation. The contention of these authorities, strengthened by clinical and pathologic proofs, is that it is only when the vessels of the splanchnic area or of the aorta above the diaphragm are diseased that high blood pressure and cardiac hypertrophy develop in arteriosclerosis. Degeneration of the peripheral vessels alone does not appear to exert this influence. After all, this is no more than we might expect if we bear in mind the all-important regulatory position which the abdominal circulation bears to general systemic blood pressure. It is interesting to note in connection with the foregoing that each one of the six cases of my series that displayed positive hypertension (170 mm. or over) yielded the physical signs of atheroma of the aorta.

It is hardly necessary to urge the importance of carefully excluding chronic nephritis in every case of arteriosclerosis with hypertension. The frequency with which chronic renal disease is associated with cardiovascular changes is well known, and no factor is so potent as nephritis in the causation of high blood pressure. If a diagnosis of chronic interstitial nephritis can be made, it is

not necessary to search further for the cause of high pressure. At the same time, it is to be remembered that greater care than ordinary is required to diagnose nephritis in cases of arteriosclerosis, owing to the fact that some degree of renal atrophy is almost always present as a consequence of the kidneys sharing in the general vascular deterioration. Casts are deprived of their diagnostic value since they are almost invariably present in the urine of the sclerotic individual. The presence of albumin and the quantitative urinary findings are of much greater value.

So far as I am aware, there exists no absolute clinical indication that will serve as a means of identifying cases of splanchnic sclerosis. Fraenkel and Hasenfeld have pointed out that corpulent persons of a sedentary mode of life are especially prone to the development of sclerosis in the abdominal vessels, thin individuals being less liable to excessive blood pressure. This observation seems to be borne out by clinical experience, yet it is manifestly impossible to establish corpulency and physical indolence as reliable criteria of the local distribution of retrograde vascular changes. Ophthalmoscopic examination may be of service by enabling us to detect changes in the retinal vessels in cases where the superficial arteries are free from gross indications of the disease, and resort should be had to this aid to diagnosis in all doubtful cases.

When the aorta above the diaphragm is seriously involved, the diagnosis is, as a rule, much easier. Alterations of the basal systolic heart sound and a clanging, reverberant quality to the second sound in the aortic area, will frequently be revealed by careful auscultation.

It is altogether likely that those rare and puzzling cases of cardiovascular disease with hypertension without commensurate involvement of the kidneys that come under observation may prove to be instances of splanchnic arteriosclerosis. In concluding this brief consideration of arteriosclerosis we may be justified in drawing the following empirical deductions from the information in hand.

DEDUCTIONS

1. The ordinary clinical type of arteriosclerosis is not necessarily accompanied by high blood pressure, a large percentage failing to show this development.

2. When high blood pressure is met with in arteriosclerosis it points to the existence either of associated renal disease or sclerosis of the splanchnic vessels and of the aorta above the diaphragm—one or both.

3. If we are able to exclude chronic interstitial nephritis in such a case, splanchnic or aortic sclerosis is to be suspected.

SECOND SERIES

The second series of observations that I wish to report comprises sixty cases of chronic Bright's disease. Only a résumé of the maximum records will be given, the full detail being reserved for a future communication.

Number of cases investigated, 60—male 34, female, 26
Average age, 51 years
Average weight, 160 pounds
Average maximum systolic blood pressure, 190 mm.
Average minimum systolic blood pressure 165 mm.
Maximum systolic blood pressure recorded in any case, 285 mm.
Minimum systolic blood pressure recorded in any case, 110 mm.

The high average pressure in this series constitutes a marked contrast to the average recorded in the preceding group of arterio-sclerosis being 190 mm. in nephritis against 148 mm. in arteriosclerosis. This furnishes

proof, if proof were needed, of the almost essential position which renal disease occupies in the causation and maintenance of morbid hypertension. The permanent character of this symptom in chronic nephritis, and the extreme difficulty of influencing it by treatment, is indicated by the high minimum systolic pressure recorded in this series (165 mm.), despite a systematic effort to reduce it in almost every case by diet, hygiene and other therapeutic measures.

An interesting outcome of my study of these cases is the evidence forthcoming as to the relation existing between albuminuria and high blood pressure.

1. Number of cases without demonstrable albuminuria, 8. Average maximum systolic pressure in these cases, 200 mm.

2. Number of cases in which the albuminuria amounted to a trace only—too minute for accurate volumetric estimation, 20. Average maximum systolic pressure in these cases, 180 mm.

3. Number of cases in which albumin was present in the urine in appreciable amount, 21. Average maximum systolic blood pressure in these cases, 197 mm.

Average amount of albumin in volumetric per cent, 3.76 per cent.

Judging from these records it would appear that no constant ratio exists between the degree of blood pressure and the intensity of the albuminuria. In the foregoing series the highest average blood pressure was noted in cases without albuminuria.

Another point of interest to determine is the relationship between the quantity of urine excreted and the degree of blood pressure. Thirty-one cases were carefully observed in this regard, the urine being collected and measured in a routine way.

Average maximum blood pressure in these cases, 180 mm.
Average daily excretion of urine, 1,554 cc.

From this it would appear that high pressure is not necessarily attended by a marked increase in urine outflow. Some detail of this observation is of sufficient interest to detain us a moment. Thus, in a case with a pressure of 285 mm., the urine equaled only 1,000 cc., another with a pressure of 265 mm. had a urine of 720 cc. of urine. On the other hand, a blood pressure of 255 mm. with 1,280 cc. of urine, one of 270 mm. with 1,000 cc. of urine. On the other hand, a blood pressure of 255 mm. has coincided with a polyuria of 5,740 cc., one of 210 mm. with 2,400 cc. of urine, one of 140 mm. with 2,400 cc. of urine, etc. No fixed relation between arterial pressure and renal activity would appear from these statistics.

Chronic Bright's disease is essentially a disease of systemic scope involving the arteries, and the heart as well as the kidneys. Arterial hypertension is one of its salient features, a fact long known and now strikingly demonstrated by blood pressure readings with instruments of precision. A systolic blood pressure of over 200 mm. is exceedingly common and cases have been reported where it has attained the extreme degree of 300 mm. The highest record I have observed using a 9 cm. arm-band was 285 mm. in a young woman with enormous cardiac hypertrophy, who died shortly after of circulatory failure and uremia. Other high systolic pressures in my records in different cases are 270 mm., 265 mm., 260 mm., 255 mm., and 235 mm. Twenty-six of the series of sixty cases displayed systolic pressures of 200 mm. and over.

Cases do occur, however, which are not accompanied by hypertension. Light instances of such character are included in my series—two of the cases showing primary low blood pressure, where treatment was unable to sustain

Notwithstanding these occasional exceptions, high blood pressure is so frequent and significant an accompaniment of contracted kidney that it constitutes one of the most valuable diagnostic indications of this disease. Urinary criteria are often obscure or may fail entirely, as we have been made aware by the researches of Emerson, Cabot and others. If the sphygmomanometer is used as a routine procedure in diagnosis, high blood pressures can not escape detection, and will put the observer on the alert. A systolic pressure of 200 mm or thereabouts points with so clear a significance to the kidneys as to reduce to a minimum the possibility of these cases escaping proper interpretation.

THE THERAPEUTIC CONTROL

It now remains, in fulfilling the title of my paper, to discuss the question of the proper management of high pressure cases. In inviting your attention to this aspect of the subject, I have a specific purpose in view, viz., the consideration of the limitations of drug therapy in the control of hypertension. I regard it as important to raise this question at the present time, owing to the increasing tendency to the use and I believe the unwise use of vasodilators in Bright's disease and other high tension disorders. In order to obtain a clearer view of the subject, a brief resumé of the clinical facts of the situation will be of service. All high blood pressure conditions are essentially characterized by the element of systemic toxemia, indeed, high blood pressure is primarily no more than a vascular reaction against the presence of toxins in the circulating blood. In Bright's disease this vascular reaction is perpetuated by the continuous character of the toxemia, and is subsequently enhanced by the uremia which results from advancing renal inadequacy. This chronic vaso-constriction leads to fibrosis of the arterial walls and impairment of their elasticity, so that the work of the heart is increased and the organ hypertrophies. Tracing the matter to its termination, we find that the permanent and progressive character of the peripheral obstruction and the limited possibilities of the heart for adjustment ultimately lead to cardiac failure, the ventricles dilate and the support of the circulation being thus impaired, secondary low pressure becomes substituted for primary high blood pressure. Progressive cardiac failure is, in theory at least, inevitably in store for every such case of cardio-renal disease.

A very different aspect is revealed if we regard the matter from the physiologic standpoint. That the extensive structural involvement and functional crippling of the kidneys must necessarily be attended with enlarged powers of circulation is obvious, since diminished powers of excretion can be compensated for only by increase in the force of the blood current in the glomerular vessels. When we consider that the energy of the heart's contraction is mainly expended in overcoming the resistance presented by the arterial blood pressure, we can easily see why, in high tension cases, the heart hypertrophies. The entire cardiovascular sequence may be regarded as a reaction of the organism against morbid influences, and as such may be looked on, within certain limits, as conservative and compensatory.

Clinical emphasis of this fact is furnished by the greater comfort and activity enjoyed by the nephritic with high tension and cardiac hypertrophy than his less fortunate brother with whom such compensation through some inherent fault of vitality fails to become established. A still more striking contrast is constituted by the misery of the stage of secondary low tension as compared with the comparative vigor and good functional

health of the period of high tension. After observing so impressive a transition one almost feels inclined to endorse the statement of Broadbent, that "it is not high tension but low tension that is to be feared in Bright's disease." Notwithstanding the truth of such an assertion in the ultimate sense, a doubt of its entire validity is forced on one by the realization that most of the functional disturbances and pains of Bright's disease arise in consequence of high tension. To this factor also may be traced most of the fatal developments which complicate its course, such as apoplexy, angina pectoris, and the dreaded terminal heart failure. A consideration of all the clinical facts must, it seems to me, impress the observer with a due sense of the value of high blood pressure to the renal invalid, yet modified with a large reservation of doubt engendered by the capacity of this element to work the ultimate undoing of the patient.

High blood pressure is a friend to the nephritic patient, but one that needs careful watching, otherwise it may betray him into many a pitfall. This is exactly the attitude, in my judgment, in which we should approach the problem of the therapeutic regulation of blood pressure. We should be watchful rather than officious. It is to be remembered that high blood pressure is a compound of two conditions, viz., increased peripheral resistance and augmented propulsive power of the heart, the former existing as a reaction against toxemia, and the latter as a response to increased work. It is self-evident that the therapeutic control of the condition must first concern itself with reducing as far as possible the systemic toxemia present. The *indicatio-causalis* is disinfection. Regulation of the diet, the fluid intake, the personal hygiene in all its details and stimulating, to a reasonable activity, all the accessory organs of elimination, must constitute the basis of the therapeutic regulation of high blood pressure in Bright's disease, and other disorders characterized by high tension. The details of these various procedures have been frequently and fully elaborated by eminent authorities and I confess myself unable to add anything of importance.

The temptation to employ active vascular medication when the sphygmomanometer has demonstrated a high blood pressure is great, and the question as to when and to what extent we are justified in resorting to such artificial means of lowering high tension is a difficult subject on which to dogmatize. I therefore submit the following propositions, with a due sense of their inadequacy, not as absolute rules to be followed in all cases, but as tentative suggestions for the medicinal treatment of hypertension as the outcome of my own experience.

SUMMARY

1 Before proceeding with the exhibition of vascular drugs, the heart and circulation should be examined with the utmost care. The points of importance to be noted are the character of the heart tones, the relative degrees of hypertrophy and dilatation, the existence of gallop-rhythm, the pulse rate in both the upright and recumbent positions and after activity. Both the systolic and diastolic blood pressures should be carefully estimated in the recumbent and the upright positions and the degree of postural variation carefully noted, in order to determine a want of vigor in the ventricle. A rapid, irregular or intermittent pulse, the presence of gallop rhythm, a mitral systolic bruit, inverse pulse and pressure record all point to cardiac inadequacy in face of the high blood pressure and may serve as indications for cardiac stimulation in place of, or in conjunction with, vaso-dilatation. Because the blood pressure is high, it does not

necessarily follow that vascular relaxants are indicated, it may be that cardiac tonics are more urgently needed

2 Excessive blood pressure of itself does not constitute an absolute indication for drug treatment, nor does it serve as reliable ground for a bad prognosis. It is remarkable how well Nature accustoms herself to severe circulatory resistance, so that cardiac integrity is maintained and symptoms remain absent for long periods, with pressures of 200 mm, and even much higher. The writer has patients at present under observation whose blood pressure, covering a period of two and three years, has seldom been below 200 mm, yet they have enjoyed a good measure of activity and freedom from symptoms. One individual whose blood pressure has ranged from 200 mm to 265 mm for one year has remained practically free from symptoms. It is well to accent the point that because the blood pressure is high it does not necessarily follow that it must be reduced by drugs in order to insure either the patient's safety or comfort.

3 Active vasodilators (nitrites) may occasionally be necessary to meet emergencies, such as stenocardia, angina pectoris, apoplexy prodromes, etc., under such circumstances they are perfectly justifiable and may be given with a freedom not at other times permissible.

4 Blood pressure may be reduced temporarily by vasodilator drugs, but it is very difficult to produce a permanent lowering except in the presence of a weak heart. This is easily understood when we remember that vascular pressure is a compound of ventricular propulsion and peripheral resistance. If you modify the latter in the presence of a strongly acting ventricle, the pressure will be maintained by the heart. Modify the peripheral resistance in the presence of a weak ventricle and the blood pressure will fall with a simultaneous increase in the pulse rate, due to inadequate efforts on the part of the heart to maintain pressure. It follows, therefore, that a material fall in blood pressure which is more than temporary, due directly to vasodilators, especially if accompanied by quickened pulse rhythm and not marked by improvement in the patient's sense of well-being, is apt to be unfavorable, being ominous of a weak heart.

5 A sustained high blood pressure (over 200 mm), if accompanied by symptoms of disquieting character, may render a course of vasodilator medication advisable. The drug chosen should be slowly and cautiously introduced, closely watching its effects on blood pressure, pulse rate and subjective state of the patient. The sudden employment of full doses of an active vasodilator is to be condemned, as it may produce serious consequences to the patient's heart and nervous system. A fall of 10 to 15 per cent is, as a rule, all that is necessary or judicious to accomplish by drugs.

6 The benefit derived from vasodilator medication can not be properly gauged by the blood pressure record. The patient's subjective comfort and more especially the pulse rate form a better index of the effect produced. The most favorable influence in my experience has been in cases where no manifest fall in blood pressure has resulted, but subjective disturbances have disappeared, and the pulse has diminished in frequency. I should say as the result of personal observation that the case which above all others will be best influenced by vasodilators is one in which the blood pressure is high (over 200 mm), and in which no direct response to the drug in the pressure record is apparent, but merely the indirect response in pulse rate and bodily comfort as above noted.

7 The employment of vasodilators in the late stages of Bright's disease with cardiac dilatation, dropsy, etc.,

is practically useless, and were it not for the fact that the vasomotor control of the peripheral circulation is too much disturbed to respond, they might do harm. The fact that the case was primarily one of high tension offers no excuse for continued reliance on these drugs under such circumstances.

GONOCOCCUS-CONJUNCTIVITIS IN ADULTS AND INFANTS

A REVIEW OF TREATMENT AND RESULTS IN ONE HUNDRED AND TWENTY-NINE CASES IN THE PHILADELPHIA GENERAL HOSPITAL DURING THE PAST SIX YEARS *

T B HOLLOWAY, MD

Instructor in Ophthalmology University of Pennsylvania Registrar
Ophthalmic Wards Philadelphia General Hospital
PHILADELPHIA.

The study of the following 129 cases of gonococcus infection of the conjunctiva, occurring in the services of Drs G E de Schweinitz, C A Oliver, H F Hansell and J W Croskey in the Philadelphia General Hospital, covers a period extending from May, 1900, to July, 1906.

For a convenience and for more accurate study such a series would naturally divide itself into two groups.

1 Those in which the infection occurred subsequent to labor, or gonococcus-conjunctivitis.

2 Those in which the infection could be traced directly to birth, or conjunctivitis neonatorum.

In using the term gonococcus-conjunctivitis in preference to gonorrheal, I follow the suggestion of Holt, because it eliminates a factor which is wholly lacking in many of these cases. Of the 129 cases that came under observation, 72 cases could be included under Group 1, or gonococcus-conjunctivitis, and 57 under Group 2, or conjunctivitis neonatorum. Of these 72 cases of the former involving 106 eyes, 54 cases occurred in adults, 44 of which were males and 10 females, while the remaining 18 cases were among children and only 4 of these were of the male sex. The cause of this apparent influence of age on the frequency of this affection in the two sexes is obvious and will be referred to indirectly later on.

Among the adults there was a bilateral involvement in 19 cases and a unilateral involvement in 35 cases and strangely enough, in the latter series the left eye was involved twice as often as the right, the actual numbers being 23 and 12. Among the children 15 cases were bilateral and 13 unilateral.

GROUP I, OR GONOCOCCUS-CONJUNCTIVITIS

Positive reports of bacteriologic examinations were obtained in 48 cases, and, while in the remaining 24 no record of such an examination could be found 16 of them had associated gonorrhea, which leaves but 8 partly unaccounted for. Of these a history of accidental infection from probably contaminated eyes was obtained in the cases of 2 female children and 1 female adult, one male adult had had two previous attacks of gonorrhea the last 6 months before his eye became involved, but stated he had no urethral discharge at the time, another male adult denied gonorrhea, but there was no record of an examination. In the remaining cases two male adults and one male child no data were recorded. It should be stated that

* Read before the Section of Ophthalmologists of Philadelphia Nov 20 1906

ords that failed to give bacteriologic data were filed before the present efficient laboratory system was instituted, and some of them were due to the failure of the resident to record results of such an examination.

On admission to the eye wards 42 of the 106 eyes were found to have some corneal involvement, while no data of the same could be found in 64. Sixteen of these 64 eyes that entered with clear cornea subsequently developed some abnormalities in this structure, so that on discharge 48 cornea had remained clear and 58 had undergone some change consequent to the gonococcus infection.

In those cases in which no vision was recorded and in which some corneal involvement had occurred, by knowing the site of the lesion and such remarks as "cornea much clouded," "macula near corneo-scleral junction, etc., a crude estimate of the probable effect on vision could be made. It should be stated that where the eye was lost or only light perception remained, such conditions were almost invariably recorded. By such procedure it was found that of these 58 eyes that suffered some corneal change, 8 were enucleated, 21 were blind or had but light perception, 10 had a moderate reduction of vision, while in 19 sight remained unimpaired or was but slightly affected. It is thus seen that where the cornea became involved it resulted in a practical loss of just 50 per cent of the number of eyes affected.

If we follow out the 16 cases in which the cornea became involved while in the house, we find that 2 eyes were enucleated, 4 were blind or had but light perception, 3 showed a moderate reduction in vision and there was but slight or no impairment in 7 eyes. It may be stated that one of these 16 eyes had a peripheral ulcer that perforated as the result of a blow from the patient's thumb, but owing to the site of the lesion he recovered with some vision. It can thus be seen that in 6 of these 16 eyes, or 37.5 per cent, there was practically a total loss of vision.

It was rather interesting to trace out how many of these 72 cases of gonococcus-conjunctivitis were due to a probable autoinfection. As above mentioned, there were 44 cases among male adults, and, of these, 32 had a urethritis, while in 12 the records failed to state its presence or absence. Of the 4 male children involved there was no record of any associated gonococcus infection, 5 of the 10 cases in female adults had the clinical manifestations of a gonorrhea, while in the remaining cases no note was made as to its presence, 6 of the 14 cases in female children also had the clinical manifestations of a gonorrhea, bacteriologic examination verifying the diagnosis in 4 cases, while in one other a suppurating bubo developed. It is not likely that any one familiar with the conditions at Blockley would take exceptions to the conservative statement that probably 90 per cent of the male adults treated for gonococcus-conjunctivitis could be shown to have an associated gonorrhea if proper measures were pursued. Also, that if carefully prepared smears were made from the cervix or from Bartholin's and Skene's glands in the female, fully 50 per cent of those delivered at the maternity and who suffered from gonococcus-conjunctivitis would show some form of associated gonococcus infection. Such being the condition of affairs, these cases do not excite the same amount of sympathy as do the children that come under observation for gonococcus-conjunctivitis where if there is a vaginitis existing in the female, it is almost invariably one of accidental infection.

All of us are familiar with the increase in recent years of gonococcus-conjunctivitis in young girls, due probably to the increased frequency of vulvo-vaginitis in these children. While vaginitis or vulvo-vaginitis in children probably belongs more accurately to gynecology, nevertheless it has a distinct bearing on ophthalmology, and, in my opinion, deserves more consideration than has been accorded to it in the past.

A number of excellent papers have been written on this subject in recent years, among which may be mentioned one by Dr. Sara Welt-Kakels¹ and another by Dr. Emmett Holt². As is now well known, this affection has a marked tendency to become epidemic in institutions for children and is exceedingly difficult to stamp out, probably more so than any of the so called infectious diseases of childhood. Holt found that in the early years of his experience with this affection in the Babies' Hospital in New York that sterilization of the napkins was not sufficient. Subsequently all cases were isolated, given special nurses and separate personal utensils, wash rags and sponges were forbidden and a separate laundry established, but with all this they were not fully able to control the disease. It was not until bacteriologic examinations were made in all children applying for admission that they obtained some control over this intractable and markedly infectious condition. He states that during eleven years but 6 cases of gonococcus-conjunctivitis developed in the house, and 4 of these were among the 273 cases of vaginitis. It is also interesting to note that there were 26 cases of gonococcus arthritis, 19 of which occurred among male children, of these 19 cases but one had a demonstrable associated gonococcus infection and that was a conjunctivitis. Smears were made from the eyes, nose, mouth and urethra with negative results. One of these cases of arthritis without other demonstrable gonococcus infection was the probable origin of subsequent cases of vaginitis that developed in the same ward.

It is but fair to assume that what has occurred in the New York institutions has likewise been going on in our own city. Without any effort at investigating the true state of affairs, I know of three hospitals in this city that have had epidemics of this affection within the past six months, and one of these was compelled to refuse admission to all female children during a portion of the past summer. In Blockley since March 27, 1906, there have been 38 cases among 183 children without the development of one case of gonococcus-conjunctivitis. This is unquestionably due in a great measure to the rigid routine now in force, as may be illustrated by the following case. A child who had had a vaginitis for some time was discharged on the urgent demands of the parents, only to return a week or some ten days later with a well-developed gonococcus infection of the conjunctiva. Among the 14 cases of gonococcus-conjunctivitis in female children occurring in the present report, the records show that 11 were admitted to the eye service from outside sources. As to the 3 that were transferred from other house services, one had vaginitis and later developed a bubo, while in the remaining two no note was made as to the existence of a vaginal discharge.

I have dwelt more fully on this condition of vulvo-vaginitis in children because it seems to me that we can no longer look on a gonococcus infection of the conjunctiva as a condition which affects the eye alone but must regard it as a possible origin of infection that may

jeopardize and mar the whole future usefulness and life of the individual so affected. While I appreciate the many difficulties that often attend the treatment in private practice of these cases of gonococcus infection of the conjunctiva, it seems to me that all such cases, especially where other children are in the house, must be treated with the same restrictions that one would institute in a case of any of the so-called infectious diseases. It also seems essential that the nurse in charge should be told of the increased susceptibility of the vaginal mucosa in children and be given definite instructions for guarding against a possible infection of the same. As can be shown by this report, and as would naturally be expected, the greatest amount of danger to the eye from a specific vaginitis does not arise among hospital cases, but in cases outside the same or where they have been discharged from these institutions before a definite cure has been established.

With a knowledge of this increasing prevalence of gonococcus infection in young girls, in my opinion, ophthalmologists would not be adopting a too radical procedure to have a vaginal examination made in these cases immediately on their admission to the general eye wards. This could be readily done at the time the child is bathed without in any way attracting the attention of the patient to the examination desired.

Among the 54 cases in the present series that occurred in adults, 6 gave histories of accidental infection, these being equally distributed between the two sexes. Of the males, one attributed the infection to a public towel, another to sleeping with a man who had a purulent discharge from the eye, and the third, the day before the eye became involved, had a foreign body taken from his eye by means of a handkerchief borrowed from a friend. Needless to say, all of these strenuously denied gonorrhea, and no record could be found of such an associated affection. As to the women, one on the day previous to her first symptoms examined the inflamed eye of a friend, another nursed a child whose eye became sore three days after birth, while the third case was probably infected by her husband who had an acute gonococcus urethritis at the time her eye became involved. This last case I sent into the hospital and it may have been an autoinfection, but, if so, her original infection was probably of recent date, for I was told she had none of the clinical manifestations of a gonorrhea one month before, at which time she was delivered of a healthy baby who failed to develop a conjunctivitis, and no instillation was used after delivery aside from boric-acid solution. By way of interest I may add that this eye showed a virulent infection and quickly ran a destructive course and was finally enucleated.

In reference to the children, as above stated, none of the 4 cases in males gave histories of an associated gonococcus infection. While in but 6 of the 14 females was there recorded a history of co-existing vaginitis.

GROUP II, CONJUNCTIVITIS NEONATORUM

Taking up the 57 cases of conjunctivitis neonatorum, we found that 24 cases developed in the house and 33 were admitted from outside sources. These were pretty evenly divided between the two sexes, 27 being males and 30 females. Inasmuch as during the past six and a half years which is the interval covered by the present series of cases, there were delivered, in the maternity wards, some 1,076 infants it is evident that 2.2 per cent of these children developed conjunctivitis neonatorum. Of the whole number of cases, 52 were bilateral

and 5 unilateral, making the total number of eyes involved 109. Records of bacteriologic examinations were found in nearly all of these cases, 50 giving positive reports, 3 were negative and in 4 cases no note could be found of such an examination, although in one of these the father was known to have a urethritis and the mother a vaginal discharge. Of those cases credited with negative reports, one had but one examination made, was born in the house, developed symptoms two days after birth and had the clinical manifestations of a conjunctival gonococcus infection, another likewise had the clinical symptoms and only one bacteriologic examination, but was admitted from the street, while to the third these same conditions would apply, with the exception that this infant had, in addition, a vaginal discharge.

It is now the rule at Blockley to obtain three negative reports of at least 24-hour intervals before discharging the case, unless a premature discharge is demanded by the parent. This seems to be a good working rule, but that it is none too rigid may be shown by one case in which three successive negative reports were obtained, only to be followed by five positive ones, before further negative results were determined. Another case gave 6 successive negative reports and then a positive one, while numerous others showed two successive negative examinations that were followed by positive ones. At this point it may be well to refer to the above-mentioned premature discharge of these cases. The records show that at least 7 cases were discharged on the demand of the parent before an effectual cure had been established, and 4 of these gave positive reports on their last bacteriologic examination. It seems to me that it would be well to follow up these cases after their departure from a municipal institution, such as the Philadelphia General Hospital, and not allow them to pass from medical observation for days or weeks at a time, as is probably often the case, this interval being largely determined by the apparent condition of the eye. This difficulty could be overcome by direct communication from the hospital to the family physician, if they have a doctor acting in this capacity, or by having these cases visited by either the so-called district physician or the medical inspector in whose district the case resided, for it is well known that medical advice given to the majority of these patients on their departure from a hospital is woefully neglected and still more frequently absolutely unheeded. In several instances where these cases were referred to outside sources, probable serious consequences were averted.

On admission to the ward of these 109 eyes the cornea was clear in 95 while 14 revealed lesions of varying degrees of intensity. While in the ward, or on discharge the cornea continued to remain free from any pathologic process in 84 eyes showing that in 11 eyes corneal changes had occurred while they were under observation.

The probable effects on vision produced by the corneal changes in the 25 eyes showing such involvement at some time during their treatment was as follows: 8 were blind or had but light perception, 7 of these cases being admitted from the street and one from the house, while the remaining 17 cases had various degrees of impairment, several probably escaping with vision unaffected. Among this last number 11 were admitted from the outside and but 3 from the house. Concerning the 11 eyes that developed corneal changes

under observation, 4 were blind or had but light perception, 3 of these entering the ward from without and one from within the house, while 7 had some probable visual defect, 5 of these entering the institution from the street and two being transferred from other wards.

The mortality in the 57 cases above reported was high, 11 of them dying after varying terms of treatment as the result of associated gastro-intestinal or pulmonary lesions. In fact it may be stated that a large number of the infants that came under observation showed marked evidences of malnutrition, and in two instances the records showed co-existing evidences of hereditary syphilis.

TREATMENT

Before referring to the specific treatment instituted in these two groups of cases, it seems appropriate to allude to a condition which frequently has a direct bearing on the ultimate result in these cases. In gonococcus infections of the conjunctiva where success or failure of treatment is usually dependent on the condition of the cornea, we should take some cognizance of one of the important factors producing a change in this structure. I refer to the excessive chemosis of the conjunctiva which is so common in this affection and which is very frequently the cause of corneal involvement by its impinging on this structure.

Probably every observer has seen cases of slight corneal haze clear up after incisions were made in a much chemosed conjunctiva. Such being the case, how easy it would be to attribute the saving of the cornea to medical rather than to surgical procedures. Hence I believe we should know in what cases scarification was used and how much of the success attained was probably due to this procedure. Unfortunately I could not find any data bearing on this important factor.

In analyzing this series I have drawn the percentages from the number of eyes rather than from the number of cases because it seems to be the more accurate, for the latter method would fail to state whether the cornea became involved in one or in both eyes and it would also probably cause other faulty conclusions as to the true conditions. The treatment sheets filed with the records show that argyrol was used routinely by but one of the four visiting chiefs. Such being the case, it is but fair to surmise that in the majority of cases the severe infections were treated with that preparation in which the attending surgeon had the most confidence. Within the past nine months I have had the privilege of hearing three of the visiting surgeons express their preference for nitrate of silver, and, judging from the frequency in which this silver salt was used by the other surgeon in attendance, he probably had the same preference.

In the cases about to be referred to, the patients were put to bed on their admission to the eye ward, appropriate treatment was instituted to correct any constitutional impairment and, needless to say, when any associated gonococcus infection existed, proper measures were employed to combat the condition. It also seems proper to allude to the faithful and efficient nursing which has been such a notable feature in this series of cases, and in fact is an essential factor in the proper management of the affection. Atropin and eserine were used in those cases in which they seemed indicated.

GROUP 1—*Gonococcus-conjunctivitis*. In these cases cold was consistently used in the early stages of the

affection unless there was some co-existing corneal involvement. Dr Miles Standish states³ that he would regard heat as preferable if the aim of the surgeon is to reduce swelling. If to affect further growth of the gonococcus, he refers to Kolle and Wassermann's statement that a growth of this organism is inhibited at the temperature of 86 F. Dr Standish took the temperature of the conjunctival sac in a patient with gonococcus conjunctivitis before the application of ice and found a temperature of 100 F. After the application of cold for 22 hours the temperature was reduced but 2 degrees, as a consequence he regards the application of cold as useless in inhibiting the growth of the organism. Dr Weeks, in referring to this statement, stated that he had reduced the temperature of the conjunctival sac to 92 F. by the application of cold which was at least sufficient to retard or limit the growth of the gonococcus. Dr de Schweinitz, in the last edition of his book, states that in a certain number of cases of gonorrheal conjunctivitis in adults, during the early stage, cold is not only most agreeable to the patient, relieving pain and irritation, but of distinct value in checking the inflammatory process and the movement of the bacteria.

In reference to the solutions used for cleansing, boric acid solution was given the preference, with potassium permanganate a close second, while bichlorid solution, formalin and silver nitrate were each used in about an equal number of cases and would rank a poor third. It may be said that in association with these sterile water and physiologic salt solution were used in some cases.

THE SALTS OF SILVER IN GONOCOCCUS-CONJUNCTIVITIS.

The various silver salts used were the nitrate in 34 cases, argyrol in 20 cases, protargol in 2, nitrate of silver with argyrol or protargol in 9, no silver preparation was used in 5, and in 2 cases the treatment sheet was missing from the records.

To obtain any idea of the effects of treatment the only cases available are those which entered the institution with clear cornea. Of these the records showed that silver nitrate was employed in 31 eyes, with subsequent involvement of the cornea in 8, or 25.8 per cent., argyrol in 20 eyes, with corneal involvement in 4, or 20 per cent., protargol in 4, with no subsequent corneal changes, nitrate of silver and argyrol in 6 eyes, with corneal involvement in 2, or 33 1/3 per cent., no silver preparation in 2, with one eye developing corneal changes, or 50 per cent., and in the case of one eye that revealed corneal involvement the treatment sheet was not among the records. It is thus shown that 16 of the 64 eyes above enumerated developed some abnormalities in the corneal tissues. Among these nitrate of silver was used in 2 eyes that were enucleated, one that was blind or had but light perception, one that had a moderate reduction of vision and 4 that had slight or no impairment. So that among the 31 eyes in which nitrate of silver was used there was a practical loss of the eye in 3 cases, or 9.67 per cent. In the eyes treated with argyrol 2 were blind or had but light perception, one had a moderate reduction, while another had but slight or no impairment of vision. Here the practical loss of eyes would equal 10 per cent. In the 2 that suffered corneal changes when treated with nitrate of silver and argyrol one had a moderate reduction and another slight or no reduction of vision. There was slight or no impairment of sight in the one case.

with corneal change where no silver preparation was used, while the process involving the cornea in the eye where no treatment sheet could be found, resulted in a blind eye

Standish³ reports 32 cases treated with protargol with corneal involvement in 34 per cent and 23 cases treated with argyrol with subsequent corneal changes in 30.5 per cent. He reports⁴ an additional 29 cases treated with argyrol, so that in all he had treated 52 cases with this preparation with subsequent corneal involvement in 22 cases or 42 per cent

Standish, since the appearance of argyrol, has given the preparation a thorough trial and evidently still regards it as our best method of exhibiting silver in gonococcus infections of the conjunctiva, despite Derby's most interesting paper on the bactericidal properties of the various silver preparations now on the market. Derby,⁵ in his laboratory experiments, used the *Staphylococcus pyogenes aureus* instead of the gonococcus owing to the difficulties attending the propagation of the latter by our present laboratory methods. He found that nitrate of silver in 0.5 per cent to 2 per cent. solutions killed the culture in 2 to 5 minutes and that an exposure of 30 seconds to a 0.5 per cent solution was sufficient to prevent its growth. Protargol in from 2 per cent to 4 per cent solutions killed in from 3 to 5 minutes, while a one-minute exposure prevented growth. Collargol in a 4 per cent solution failed to prevent a growth after an exposure of an hour. Ichthargan and argentamin in weak solutions both killed the growth after an exposure of 4 minutes, but he adds that both are very irritating.

He states that argyrol's bactericidal properties are very weak and that a large series of observations gave a growth after an exposure of 1 to 2 hours to solutions the strength of which varied from 10 per cent to 50 per cent. He calls attention to the experiments of Verhoeff and confirms his statements that if human blood serum be added to solutions of sodium aurate and protargol their bactericidal properties are destroyed. He also states that he found that the action of Lugol's solution and bichlorid solution of the strength of 1:1000 was much retarded by serum such as hydrocele fluid and bovine blood serum.

GROUP 2—*Conjunctivitis Neonatorum*. Here I deem it necessary again to refer to the general nutrition of the majority of the cases that come under observation in the Philadelphia General Hospital, a factor which has no little bearing on the ocular results in these cases.

Inasmuch as the vast majority of these infants come from the lowest social strata in the city, poverty, ignorance and negligence are responsible for the advanced stages of malnutrition so frequently seen on their admission and renders a prognosis grave, not only from an ocular aspect, but from a systemic one as well.

In taking up the cases in this group we find that cold was used in the initial stages in the majority of cases, but not as consistently as in Group 1. For cleansing, boric acid was used in 36 cases, potassium permanganate in 14, formalin in 5 and bichlorid in 2 cases. Here, as in Group 1, sterile water and physiologic salt solution were used with the above in some cases.

THE SILVER SALTS IN CONJUNCTIVITIS NEONATORUM

As to silver, the nitrate was used in 32 cases, argyrol in 8, nitrate of silver and argyrol in 9, the nitrate and

protargol in 1 and no silver preparation in 7 cases. It is interesting to note the result in this last group for these 7 cases treated without any silver preparation recovered with the cornea intact or at least no note of any lesion could be found on the records. Whether the result obtained in these few cases was influenced by the less amount of manipulation required, by the character of the infection or by the few cases reported, can not be determined, but probably all were contributing factors.

Referring again to those instances in which the eye was free from corneal involvement on admission, we find that 50 of these eyes were treated with nitrate of silver, with subsequent corneal involvement in 6, or 12 per cent, 14 eyes were treated with argyrol, in which but 1 developed corneal changes, or 7.14 per cent, 16 with nitrate of silver and argyrol, with 2 showing corneal changes, or 12.5 per cent, 2 with nitrate of silver and protargol, in both of which the cornea became involved, while in 13 eyes no silver preparation was used and, as above stated, none of these developed abnormalities of the cornea. Standish reports 50 cases treated with nitrate of silver with corneal involvement in 5.6 per cent, 150 cases treated with protargol, with corneal changes in 2 per cent, and 201 cases with argyrol in which only 4 cases, or 2 per cent, developed some corneal abnormality.

In the 11 eyes that developed some change in the corneal structure while under observation, the treatment was as follows. With nitrate of silver one eye was blind or had but light perception, while in 5 there were varying degrees or no visual impairment. This gives a total loss of vision in 2 per cent of the eyes so treated.

With argyrol one eye became blind or a total loss of vision in 7.14 per cent. In the 2 eyes with corneal involvement treated with nitrate of silver and argyrol, neither resulted in a destruction of vision while in the 2 treated with nitrate of silver and protargol the corneal changes were extensive and produced blind eyes.

In conclusion, it may be noted that at Blockley both the Crede method and the instillation of argyrol are used at the maternity. At the University maternity, argyrol has been consistently used during the past year or two, while at the Preston Retreat I have been told that argyrol was abandoned about one year ago and that the Credé method is now exclusively employed. At the Maternity Hospital the Credé method alone is used.

A CONTRIBUTION TO THE STUDY OF THE OPSONINS

ERNEST A. KNORR, M.D.
BALTIMORE

While engaged in the study of the opsonins there arose the following questions which have not received appropriate consideration in previous publications and which, nevertheless, are deemed important.

1. What influence has the strength of the bacterial emulsion on the phagocytic index and the percentage of phagocytizing cells?

To this end an emulsion of the *Staphylococcus aureus* of definite strength was prepared and progressively diluted, the serum and corpuscles came from a healthy individual. The results are shown in Table 1.

In this table it will be observed that the phagocytic index and the percentage of phagocytizing cells are, generally speaking, in direct proportion to the strength of the bacterial emulsion. This influence

368 750	0 85	42
270 500	0 80	57
138 250	0 58	80
138 250	0 58	30
60,125	0 40	20

strength of the emulsion is further shown in Table 2, in which both the opsonic bacillary index (Wright) and the percentage index (Simon) are worked out

TABLE 2

No of cocci per c mm	No of cocci per leucocyte		Percent of phagocytizing cells		Wright's Index	Simon's Index.
	Patient's serum	Pool	Patient's serum	Pool		
8 750 000	2 54	3 15	87	82	0 80	0 94
1 875 000	1 08	1 00	68	70	0 88	0 85
937 500	1 26	1 80	68	65	0 90	0 89
108 750	1 02	1 78	50	45	1 30	1 11
234 375	0 73	0 71	87	88	1 02	1 05

2 What effect has the period of incubation on phagocytosis? To determine this point charged pipettes were incubated for varying periods of time at 39 C. The phagocytic index and the percentage of phagocytizing cells were then determined as usual. The strength of the bacterial emulsion corresponded to 937,500 cocci per c mm.

TABLE 3

Period of incubation	No of cocci per leucocyte.	Percent of phagocytizing cells
15 minutes	1 30	65
30 minutes	2 24	65
45 minutes	2 80	87
60 minutes	4 00	90
90 minutes	4 01	90

The results show that with a long exposure both the phagocytic index and the percentage of phagocytizing cells undergo a distinct increase, the maximum being reached in one hour. After two hours the degenerative changes in the leucocytes become so extensive that accurate observations are rendered impossible.

3 Does phagocytosis occur at room temperature, viz, from 13 to 15 C? Pipettes were charged as usual and left for varying periods of time as indicated in Table 4.

TABLE 4

Period of exposure.	No of cocci per leucocyte	Percent of phagocytizing cells
One hour	0 18	14
Two hours	0 70	35
Three hours	0 80	36
Six hours	1 22	47

This shows that phagocytosis does occur, but that an exposure of fully six hours is necessary before the extent of phagocytosis reaches those figures which we usually see after fifteen minutes exposure at body temperature.

4 What effect has the number of persons composing the pool on the opsonic index? In determining the above question the sera of ten healthy persons were collected and mixed in equal proportions, thus giving ten pools, containing from one to ten sera. With these the opsonic index was determined, using an emulsion of the *Staphylococcus aureus*. The normal serum gave 56 per cent of phagocytizing cells, with an average number of cocci per leucocyte of 1 14.

Table 4 shows plainly the advantages of Simon's percentage index over Wright's bacillary index, which latter will vary to a greater extent if cells are included in the

count in which maximal numbers of organisms are contained, which is frequently almost unavoidable, owing to the difficulties which attend the preparation of perfectly homogenous emulsions. With specially satisfactory emulsions the two indices practically coincide. It is apparent that Simon's index is thus a check on the bacillary index.

TABLE 5

Pool	Percent of phagocytizing cells.	No cocci per leucocyte	Wright's Index.	Simon's Index.
One person	02	1 24	0 91	0 90
Two persons	57	1 18	0 98	0 98
Three persons	60	1 42	0 80	0 93
Four persons	50	1 16	0 98	1 00
Five persons	04	1 19	0 85	0 87
Six persons	71	1 52	0 75	0 79
Seven persons	58	1 11	1 00	0 90
Eight persons	60	1 40	0 81	0 93
Nine persons	08	1 48	0 77	0 82
Ten persons	71	1 52	0 75	0 79

If we interpret the finding in Table 5 in this sense, the variations in Wright's index are readily explained, and it follows that a simple or at most a double mixed pool is necessary for ordinary purposes, a conclusion to which I believe Wright himself has come.

5 What effect has the age of the culture on phagocytosis? An emulsion (a) was made from a 46-hours-old culture containing 2,350,000 cocci per c mm, and a second emulsion (b) from a 42-days growth containing 3,380,000 cocci per c mm. In the first instance the average number of cocci per leucocyte was 4 84 and the percentage of phagocytizing cells 95, while in the second case the phagocytic index was 9 6 and the percentage of phagocytizing cells 99. It follows that the aging of the culture does not lead to a drop in the phagocytic or percentage index.

6 What effect has boiling and the addition of preservatives to bacterial emulsions on phagocytosis? The above emulsion (a) was placed in boiling water for 30 minutes, after which the phagocytic index was 7 18 and the percentage of phagocytizing cells 96. This heated culture was then preserved for 3 days with about 0 25 per cent of lysol. The average number of cocci per leucocyte was now 2 81 and the percentage of phagocytizing cells 77.

One portion of emulsion (b) was similarly preserved with thymol and the remainder with chloroform for 3 days. In the first instance the phagocytic index was 8 03 and the percentage of phagocytizing cells 95, and in the second 8 43 and 98 respectively.

This shows that boiling, thymol and chloroform have no inhibitory effect on the opsonic values, so far as the usual technic goes, while lysol seems to produce a decrease.

7 How long do the opsonins remain active? In other words, how long can the serum be kept before examination using the small quantities which are usually taken?

The results show that the serum loses one-half of its opsonic power in 24 hours, after this there is practically no further loss in the following 24 hours. The value then rapidly drops, but, however, does not wholly disappear until after 5 days. It is to be noted that the serum was collected and kept in a sterile condition. (Table 6.)

How long do the corpuscles retain their capacity for

TABLE 6

Age	Phagocytic Index.	Percent of phagocytizing cells.
Fresh serum	4 08	92
Twenty four hours old	1 92	72
Two days old	1 20	70
Three days old	0 39	22
Four days old	0 39	10
Five days old	0 14	8

phagocytosis? In this instance also the corpuscles were kept sterile and fresh serum used in every case (Table 7)

TABLE 7

Age	Phagocytic Index	Percent of phagocytizing cells
Fresh corpuscles	1 09	45
Twenty four hours old	0 61	29
Two days old	0 30	18
Four days old	0 00	8

The results show that only fresh corpuscles can be used in opsonic work, and my experience has been that after six hours many of the cells are dead and that fallacious results are obtained if such cells are used

9 How many cells must be counted in order to obtain a satisfactory result? Emulsions of various strengths were prepared, and both the bacillary and Simon's index determined for 25, 50, 75, 100, 150, 200, 300 and 400 cells respectively The results are shown in Table 8

TABLE 8

A. Emulsion of 2 000 000 cocci per c.mm		
Cells counted	Wright's Index	Simon's Index
25	1 00	1 26
50	0 97	1 00
75	0 96	1 00
100	1 09	1 02
150	1 16	1 12
200	1 23	1 20
300	1 18	1 11
400	1 27	1 16
B. Emulsion of 660 006 cocci per c.mm		
Cells counted	Wright's Index	Simon's Index
25	1 85	1 18
50	1 32	1 16
75	1 03	1 00
100	1 25	1 02
150	1 80	1 02
200	1 12	0 97
300	1 13	1 04
400	1 00	1 00
C. Emulsion of 222 222 cocci per c.mm		
Cells counted	Wright's Index	Simon's Index
25	1 20	0 60
50	1 02	1 14
75	1 75	1 27
100	1 75	1 20
150	2 21	1 60
200	2 15	1 70
300	2 00	1 62
D. Emulsion of 74 074 cocci per c.mm		
Cells counted	Wright's Index	Simon's Index
25	No Index	No Index
50	0 60	1 00
75	0 60	0 62
100	0 57	0 70
150	1 14	1 26
200	1 13	1 15
300	0 95	0 98
400	1 05	1 11

The results show that with weak emulsions the chances of error are greater than with stronger emulsions, bearing in mind that with too rich emulsions counting becomes difficult, if not impossible

In these experiments, likewise, the advantage of Simon's index is at once apparent, although with the weaker emulsions it also becomes somewhat uncertain

In conclusion I wish to express my appreciation to Dr Charles E Simon, at whose suggestion the above experiments were undertaken

1727 West Lombard Street

GONORRHEAL PROSTATITIS *

J BAYARD CLARK, M.D

NEW YORK CITY

The constancy with which prostatitis occurs when gonorrhea invades the posterior urethra, and the persistent nature of that inflammation after the subjective symptoms, and the more evident of the objective symptoms, have subsided, give this condition the right to more consideration

That a gonorrheal inflammation of the posterior urethra ever occurs without involving the prostatic ducts to a greater or less degree seems unlikely Anatomically there is little to invite a posterior urethritis to the exclusion of the prostate The character of the epithelia, the scarcity of mucous glands, and the almost vertical direction of the canal, which is distended so much of the time with urine and made one with the bladder cavity, are factors against a theory that the prostatic urethra can be affected with a gonorrheal infection without the prostate participating

Acute gonorrheal prostatitis—the division of this affection into the catarrhal, the follicular, and the parenchymatous forms—may well be accepted as expressing the clinical varieties, providing the tendency of one form to merge into another is appreciated

CATARRHAL PROSTATITIS

This form is by far the most frequent of the acute varieties It is highly probable that with every posterior gonorrhea there is some involvement of the prostate and though it may extend but a short distance into the prostatic ducts and be relatively mild, it is obvious that its existence should be appreciated

The symptoms of catarrhal prostatitis go hand in hand with the symptoms of posterior urethritis—the increased desire to urinate, the cloudiness of both portions of urine, and the characteristic small, round and comma-shaped shreds which so often appear These filaments, when examined microscopically, are usually small plugs or casts made up of mucus, pus cells, cuboidal and cylindrical epithelia, and gonococci The prostatic origin of these shreds is not difficult to prove If after a portion of the urine is voided light digital pressure is made on the prostate, the shreds are squeezed into the urethra and carried out with the urine which is then passed

The danger of manipulating the prostate during an acute inflammation of that organ is ever to be borne in mind on account of its tendency to produce not only an acute epididymitis but an extension of the prostatic involvement as well The clearing up of the acute posterior urethritis is, I believe, seldom accompanied with a resolution of the catarrhal prostatitis Its tendency is to go on to a chronic condition

The diagnosis must usually be made by the urine, as examination of the gland by the rectum frequently fails to show any change in size or consistence or give any areas of tenderness

FOLLICULAR PROSTATITIS

This may be an extension of the catarrhal form or it may follow directly the onset of an acute urethritis posterior The process of inflammation extends in a selective way along certain ducts toward the periphery of the gland and usually in its upper part there to establish by purulent or cystic distension of the alveoli, the small nodules or tender areas detected by digital exami-

* Read before the Section on Genito-Urinary Diseases of the New York Academy of Medicine November 21 1905

Induced Hyperemia in Treatment of Acute Infections.—G Fichera publishes in the *Policlinico*, xiv, 6, 1907, the results of extensive experimental and clinical research on the efficacy and the mechanism of Biers stasis hyperemia His article is illustrated and is accompanied by nearly 8 pages of international bibliography on the subject His conclusions are to the effect that the hyperemia induced retards the circulation through the part, while the transudation and diapedesis impede the general invasion of the organism by the bacilli At the same time as the medium becomes less favorable for them they fall a prey to the migrating leucocytes as phagocytosis is exceptionally active under these conditions

nation The symptoms accompanying this phase of acute prostatitis are not unlike those of the previous variety—increased and usually painful urination, the pain intensified at the close of the act, both urines cloudy, and the comma-shaped shreds, which are seldom absent

Follicular prostatitis, like the catarrhal, tends to become chronic The treatment during the acute stage consists in the treatment of the urethritis, by the avoidance of bodily exercise, by the avoidance of local manipulation of the prostate, and by the avoidance of constipation, and the institution of such measures as will tend to reduce the existing congestion and inflammation

PARENCHYMATOUS PROSTATITIS

In its milder forms this is clinically identified by the hyperemia or congestion of the entire gland By the rectum the prostate is felt to be evenly swollen and smooth, and its consistence is elastic or edematous, though, from time to time, only one of the lateral lobes is found thus affected

Although the organ is distinctly sensitive to pressure there is no sharp pain, but the patient experiences a sense of fullness in the perineum Urination is made more difficult and painful and defecation is attended with pain and discomfort There is no fever The condition under appropriate treatment may subside in a few days and all subjective symptoms disappear or it may go on to chronic prostatitis or take on the progressive course which we recognize as the severer form of parenchymatous prostatitis, and which at times ends in abscess formation Here we find a patient suffering with a painful

of pressure and swelling in the perineum and rectum Micturition usually becomes difficult and painful, though in some cases this is absent, while in other cases there is complete retention Pain may radiate to the glans penis, to the thighs or across the back Defecation may be very painful and erections and pollutions distressing Fever may be present and accompanied by chills, though Casper had 21 cases which went on to prostatic abscess, and among them only four had a rise of temperature On palpation the neighboring parts are found extremely sensitive, while the rectal examination of the prostate is exquisitely painful

The gland is found swollen to twice or four times its normal size It feels hot and is hard and tense, being sharply defined against the surrounding softer structures Its surface is smooth, seldom irregular and one side only may be affected

Notwithstanding the severity of the process, it may not go on to abscess formation, but, in from one to two weeks, the symptoms may subside and resolution take place This, fortunately, occurs in the larger proportion of cases, which then go on to a chronic condition

When suppuration does occur, the clinical picture usually becomes intensified The pain on urination is increased ischuria is common and the prostate becomes a pulsating and painful tumor Rectal tenesmus is constant The temperature rises the tongue becomes dry thirst is intense and the appetite gone, headache and backache ensue Thrombosis of the periprostatic venous plexus or in the prostatic veins themselves may take place and go on to a typical occurrence of pyemia It is usually not difficult to detect suppuration in the inflamed prostate

Surgical interference is at this moment demanded If it is delayed, the abscess usually empties itself and most commonly into the urethra The urine then be-

comes loaded with the products of suppuration, and the fever, the dysuria and the rectal tenesmus rapidly subside It may be that the evacuation of pus is incomplete, and in this instance the disappearance of symptoms is delayed and the process may proceed to a chronic condition Complications, such as infiltration of urine, gangrene, chronic septicemia, or fistula, at times ensue

Next in frequency to the urethra as an exit for the pus, come the rectum and the perineum in the order given In Segond's collection of 102 cases, perforation occurred 64 times into the urethra, 43 times into the rectum, 15 times into the perineum, 8 times into the ischio-rectal space, 3 times in the inguinal region, twice through the obturator foramen and once each through the navel, through the ischiatic foramen, at the border of a false rib, into the abdominal cavity and into the space of Retzius The after-results of prostatic abscess may be chronic suppuration, neurasthenia, impotentia generandi, stricture of the rectum, etc It is to be borne in mind that besides the complications which not infrequently attend suppurative prostatitis the mortality is considerable In the 102 cases of Segond's referred to above, there was a 34 per cent death rate This is, however, considered very much too high according to other observers

The treatment of these severer forms of parenchymatous prostatitis is both general and local The patient should be put to bed a light diet given and the lower bowel kept empty Urinary antiseptics should be given and warm applications or sitz baths prescribed Early in the process the direct application of cold to the prostate by means of one of the instruments designed for that purpose is often apparently of great benefit The severer pain and dysuria must be controlled by opium or its alkaloids A complete retention of urine demands catheterization With the breaking down of the process into abscess formation comes the necessity for surgical relief

CHRONIC PROSTATITIS

This condition assumes a degree of importance which the acute varieties cannot approach On the score of infectiousness acute prostatitis is little to be feared, as the active and painful nature of the condition renders the individual practically incapable of sexual intercourse On the other hand, chronic prostatitis, which is so often wholly devoid of subjective symptoms, is probably a fertile source of the infection of women In this connection it is to be especially noted that the great majority if not all of the acute inflammations of the prostate pass on to a chronic condition

To divide chronic prostatitis, of which the chief etiologic factor is the gonococcus, into pathological and clinical varieties is of little moment Clinically, the disease gives little evidence that can be put down as surely characteristic of one or another variety, and pathologically we usually find, in the same prostate, changes belonging to various forms of inflammation At the same time the fact is not to be overlooked that chronic gonorrheal prostatitis varies much in degree and in resistance to treatment

Symptoms—The majority of cases of chronic prostatitis run a mild course without subjective symptoms the patients voiding perfectly clear urine In others the symptoms are so well masked by the persistence of a urethritis that a precise diagnosis is difficult In the remaining class however some of the characteristic symptoms appear Disturbance of urination, the changes in the sexual function, abnormal sensations, referred pains

neurasthenia, suffering from pains across the back, down the thighs or in the testicles, constipation, pain before and after defecation, headache and mental depression. With some patients frequency of micturition, which may be attended with pain, is the most prominent symptom and to this may be added the sense of not having completely emptied the bladder. With other patients the disturbances of the sexual function seems to stand out as the chief difficulty, such as absence of normal sensation at the moment of ejaculation, pain with the seminal discharge, distressing and persistent erections at night, premature ejaculations and decreasing sexual ability. It is in these individuals that we most frequently see the best marked types of sexual neurasthenia.

Some authors hold that prostaticorrhea is one of the chief symptoms of chronic prostatitis. The writer's experience coincides with those who consider prostaticorrhea as an unusual occurrence in this condition. The combination of chronic prostatitis and cystitis is by no means uncommon. In these cases the treatment of cystitis without recognition of the prostatitis, and attention to it, proves very disappointing.

All cases of persistent urethral discharge or a persistent morning drop or those cases with a chronic and constantly recurring discharge, should be suspected and examined for prostatitis.

Diagnosis—Although the subjective symptoms give a valuable clue to the condition, an exact diagnosis cannot be made without digital exploration of the prostate by the rectum and what is more important, microscopic examination of the expressed prostatic secretion.

A knowledge of how the normal gland should feel in the different periods of life is essential to the appreciation of size, configuration, consistence and sensitiveness of the diseased organ. The changes in prostatitis noted by palpation are many. The gland is usually larger than normal, although this is by no means always the case, for in some instances it is found markedly atrophic. Frequently one lateral lobe only is affected, or the organ may be very irregular in outline and feel as though it were made up of many lobes. Nodulation may be abundant or there may be but one or two nodes and these may vary in size, consistence and location, but they are usually about the size of a pea, hard, and situated nearer the upper part of the gland. The general enlargement of the prostate which results from a parenchymatous prostatitis usually gives an edematous feel to the organ, having lost its normal firm and elastic consistence. It becomes, as some authors put it, flabby, this varying much in degree.

The condition following the follicular form is varied. The gland, as a rule, is not so large as in the postparenchymatous condition, but is usually harder, while here and there distinctly soft spots may be felt and the nodules are few or many, localized or scattered, as the case may be. Where there has been suppuration with escape of the pus, involving the whole gland, or one lateral lobe, or as in the follicular variety, small areas the characteristic changes of contraction and firm cicatrices result and give that sense to the examining finger. In other cases there is no change in the prostate that can be appreciated by digital exploration, and no degree of sensitiveness, in these cases the diagnosis depends alone on the study of the prostatic fluid. Pain on palpation of the prostate is generally a sign of disease but by no means always and painful areas are not infrequently found in prostates otherwise negative to the digital touch.

The secretion which is collected at the external urinary meatus upon digital compression of the prostate, after

the urethra has been cleansed by urination or irrigation, consists normally of a thin, milky fluid, at times slightly viscid. Its specific gravity is but little higher than that of water, it is usually faintly alkaline to the litmus test, and consists microscopically of lecithin globules, varying in size and usually present in great numbers, and epithelia which are partly cuboidal and partly columnar. A few leucocytes are normally present and occasionally some red corpuscles. Hyaline bodies of considerable diameter and the so-called *corpora amylacea* are not infrequently seen.

The changes from normal which most commonly take place in the prostatic fluid are in consistence and color. It becomes thicker, often flaky and yellowish or greenish-yellow from the addition of pus. Under the microscope there are added to the field of lecithin bodies pus corpuscles in varying numbers, scattered or in clumps, depending on the extent or kind of inflammation. In like manner epithelia from the ducts and alveoli are added, and these in different stages of degeneration. Fat globules may be seen free in the field or in the epithelia or pus cells.

The *corpora amylacea* seem to be much less frequently seen in gonorrheal prostatitis. It is to be especially remembered that as long as the presence of pus cells can be demonstrated a pathologic condition exists. Gonococci may be found in the pus cells and the fact that we cannot find them is not proof of their complete disappearance.

Prognosis—When is the danger of infecting others past? When is a chronic gonorrheal prostatitis cured? To these questions no clean cut answer can be given.

When the urine contains no more shreds or other abnormal elements, and the prostatic fluid is free from pus cells, and repeated search for gonococci with the microscope and by culture test fails, certainly we have no grounds on which to maintain that the patient is still afflicted with an infectious disease. But on the other hand, we cannot positively say that such individuals have become noninfectious.

After a few months or a year we find in a large number of the cases, the presence of gonococci impossible of proof. Unfortunately, the mixed infection, which almost always complicates these cases, renders the task of clearing the prostatic fluid of pus cells exceedingly difficult, if not impossible. Although it has been stated that so long as pus cells remain a pathologic condition exists, yet experience has taught that these cases are by no means always infectious.

From the observation of 120 cases, von Notthafft has come to the following conclusions:

1 In the second half year after the infection there was 73 per cent of the cases in which the gonococci could be proved to be present in the prostatic secretion. In the third half year this percentage fell to 50. In the fourth half year to 18, in the third year to 6. From the end of the third year no gonococci could be found in the prostatic secretion.

2 In the second half year there were other bacteria besides gonococci found in the prostatic secretion. In the fourth half year there were no cases in which a pure gonococcal infection could be demonstrated.

In a few patients from whom the writer made cultures the results were in accord with Notthafft's series. In 7 cases mixed infection was concerned. In 10 cases the writer's cases were gonococci. In 10 cases scope or culture yet in five cases considerably over 50 per cent of the cases 18 months old. In 7 out of 10

growth of *Staphylococcus albus*, and in two of these there was added a growth of *Bacillus xerosis*. In one case there was no growth.

The conclusions to be drawn are that there is difficulty in proving the presence of gonococci in these older cases of chronic gonorrhoeal prostatitis, and that other organisms play an active part in the bacteriology of this affection.

Treatment—Where a urethritis exists, either anterior or posterior, therapeutic measures designed for the cure of this condition must be instituted. For the treatment of the chronically diseased prostate, massage of that organ by the rectum, constitutes the most important element of the treatment. The bladder should be filled with some such mildly astringent antiseptic as protargol, $\frac{1}{2}$ of 1 per cent solution. In very many cases dilatation of the prostatic urethra, either by sound or dilator, is helpful in the treatment by virtue of the internal massage and stretching it exerts, especially on the mouths of the prostatic ducts.

Digital massage, to be useful, must be done in a systematic and purposeful manner. Starting at the external upper part of the lateral lobe, the massaging finger-tip works its way toward the median line of the gland, again it is carried to the external border, immediately below the previous path of massage, and again worked toward the center. This is continued until each lateral lobe has been thoroughly gone over. Then the finger is swept over the lateral lobes downward and toward the center, emphasizing the pressure brought to bear on the median line, that the secretion may thus better be expressed into the urethra. The patient then voids the solution which has been left in the bladder, which thus washes out the urethra and comes in contact with the recently emptied prostatic ducts, which as some think, may take up some of the solution on the principle of a sponge which has been compressed and is allowed to expand while in contact with a fluid. This massage has two distinctly beneficial elements. It empties the alveoli and their ducts of the perverted secretions which have accumulated, and it stimulates a more active circulation throughout the entire gland.

Again a warning against the danger of extending the process in massaging a prostate in which there still exists any active inflammation.

The massage which is done very gently at first, should be repeated once, twice or sometimes three times a week, depending on the necessity of the case. A few weeks' period of treatment for the milder cases up to many months of treatment for the severer cases, is required. Besides massage such measures as electricity or heat and cold applied to the prostate may in certain instances be helpful. Medicinal suppositories as ichthyol, have a useful place in the treatment of prostatitis.

The advancement of the patients' general condition cannot be neglected and freedom from worry or other untoward influences must be secured. Favorable progress of the prostatitis is appreciated partly by the changes in the gland felt by the rectum, but more especially by the study of the prostatic elements microscopically. Improvement in subjective symptoms is unreliable.

Although the treatment is usually long and trying taxing the patience of the physician and his patient, yet with well directed and conscientious care on the part of the physician and earnest cooperation on the part of the patient the latter will be freed, in the greater majority of cases from the danger of infectiousness and other consequences of chronic gonorrhoeal prostatitis.

TRAUMATIC NEUROSIS *

PHILIP ZENNER, A.M., M.D.

Professor of Neurology in the Medical College of Ohio
CINCINNATI.

Traumatic neurosis is a nervous disease following injury, in which there is no demonstrable structural lesion of the nervous system. The symptoms are much like those of the common functional diseases of the nervous system, and may be spoken of as traumatic hysteria or traumatic neurasthenia. Commonly, however, we find symptoms of both of these disorders in the same patient and not rarely the clinical picture may not be that of either of them.

Litigation is a frequent complication which materially affects the clinical history. It, not rarely, warps the judgment of the physician, and may doubly influence the patient, the many attendant conditions disastrously affecting his nervous system, while the money dangling over his head leads him, consciously or unconsciously, to distort his symptoms.

The following cases are typical of a common form of traumatic neurosis, and a long period of observation gives special value to their study. I append some consideration of special points of interest relating to the disease.

CASE 1—Mrs. L., music teacher, aged 45 at time of injury, November, 1899.

History—She was in a street car collision, a runaway car colliding with the one in which she was riding. A physician found her fifteen or thirty minutes later lying on the floor of the car, in a dazed condition, with several cuts on her face and forehead, made by broken glass. She was confined to bed for one or two months and invalided thereafter. Her chief symptoms, and those she still presented when I saw her, were of a neurasthenic type. Insomnia, restlessness, irritability, great sensitiveness, weak memory, lack of endurance, and incapacity for thought or action. In addition she was very weak on her feet, had little use of the right hand, and there was a certain immobility of the head, because its movement caused pain in the cervical spine.

Examination—I examined the patient in February, 1901, fifteen months after the injury had been received. The examination was made at the request of her lawyer, as a suit for damages had been instituted. The marked objective symptoms were a right hemiplegia and hemianesthesia. The motor paralysis affected only the arm and leg, and not the face. The gait was characteristic of hysteria, the paralyzed limb dragging behind instead of presenting the outward sweep of ordinary hemiplegia. The sensory loss was of all qualities of sensation, touch, pain, temperature and muscular sense. In the face the anesthesia reached to the median line. On the extremities only a part was affected. On the arm the ulnar side was anesthetic, the radial was normal. On the leg the outer side was anesthetic the inner was normal. The special senses were also affected there was loss of taste and smell on the right side, deafness of the right ear and amblyopia of the right eye. There was, also, anesthesia of the mucous membranes on the right side, and, still more striking, loss of the corneal, nasal and pharyngeal reflexes. For instance, strong snuff in the right nostril gave no response, while the same applied to the left caused immediate and violent sneezing. The deep reflexes, knee-jerks as well as pupillary reactions and optic discs were normal.

As this case was in litigation tests were made to determine the genuineness of the symptoms. That of the nasal reflexes has already been mentioned. The patient complained of great tenderness over the cervical spine and the genuineness of this symptom was proved by the considerable acceleration of the pulse caused by pressure over the seat of tenderness. This is called the Mannkopf symptom. In the same manner one could

* Read before the Cincinnati Academy of Medicine Dec. 7, 1906.

demonstrate the feebleness of the patient, for a very little exertion caused considerable acceleration of the pulse. The latter was also a test of the genuineness of the anesthesia, for when I applied a strong current of electricity with the brush to the normal skin, the pulse was again accelerated, while the same, or even a stronger current, applied to the anesthetic skin did not affect the pulse.

The deafness and amblyopia were tested by Ziehen's method. I tested the amblyopic eye, also, by placing prisms and opaque discs before the sound one. All these tests proved the genuineness of the symptoms.

The lawsuit was held about one year after the time of this examination. In the meantime the changes that had taken place in the patient's condition had been rather for the worse.

The litigation resulted in a large award for damages, which was paid at once. I saw the patient several times in the next few months, but there was little if any improvement during that time. I recently heard from her physician—she does not live in Cincinnati—and he said that the motor paralysis had entirely disappeared, perhaps had done so two years after litigation was over, but he could tell me nothing regarding the anesthesia.

I have no knowledge of the objective symptoms presented by the patient prior to the time of my first examination, but, from what I could learn, I have no doubt they were more marked when I saw her than at an earlier period. Probably her condition became worse after litigation had been decided on. She became rather worse during the year between the time of my examination and the time of the trial. Thereafter, in the course of about two years, many or all of her symptoms disappeared. There can be no doubt of the marked influence of litigation on the course and progress of the case. At the time of my examination it appeared to me that there was a tendency to exaggeration of symptoms and that there was more muscular strength than she cared to make manifest. But there are no simple tests of the genuineness of motor paresis as there are of sensory impairment. The motor paralysis has disappeared. It would be of interest to know if the same is true of the sensory paralysis.

CASE 2—Mrs. W., aged 48 at the time of injury, July, 1901, was injured in stepping off a car at night into a broken street. She fell backward, striking the back of her neck. She first called in her physician three days after the accident. He found bruises over the left shoulder and arm, and that she was suffering with pain in the left side and back of the neck. I have no accurate knowledge of the further development of symptoms, but she had various nervous symptoms and was finally sent to the Bethesda Hospital. She was in the hospital from October, 1901, to May, 1902, part of that time having decided mental symptoms, but she was finally sent home much improved.

Examination—I saw her about two years after the injury, at the request of her lawyer, as a suit for damages was about to be tried. She presented the appearance of health, but was restless, irritable and excitable. She complained, also, of being unable to attend to her duties as housekeeper, and of having a poor memory, and much pain. There was great tenderness over some of the cervical and lumbar vertebrae, her gait was feeble, the dynamometer indicated 60 as the strength of the right hand, and 26 as that of the left. There was loss of the sense of pain over the whole of the left side, narrowing of the field of vision, loss of smell in the left nostril, and loss of pharyngeal and nasal reflexes on the left side. The knee-jerk, Achilles tendon reflex, and pupillary reactions were normal.

The genuineness of some of these symptoms, tenderness, analgesia, nasal reflex, etc., were demonstrated in the manner described in the report of the first patient.

As the result of the lawsuit the patient was awarded a large sum for damages. The case was appealed, and eighteen months

later a settlement was made for less than one-half the sum awarded her by the jury.

Later Examinations—I had the opportunity to make two further examinations of this patient, the first a year after the trial, but before a settlement had been made, the other recently, one and a half years after the settlement. At the time of the first examination she had improved very materially, but she was still neurasthenic and the objective symptoms were still present, though less marked. At the last examination, while there was even a greater improvement, she still complained that she was not so well as before the injury, and that there was some tenderness over the spine, and a degree of hemianalgesia.

It will be remembered that the patient did not consult a physician until three days after her injury and that the marked nervous symptoms appeared at a later date. I do not know what influences may have played a part in the development of her disease, but we can not go far amiss if we attribute to litigation a part of the condition found when I examined her.

CASE 3—Miss T., aged 28 at time of injury, April, 1900, was caught and dragged by a rope which happened to be hanging from a passing wagon. She did not lose consciousness, but was considerably bruised, especially over the left hip and knee. She suffered much, was confined to bed for several months, and since then had symptoms much like those presented at the time of my examination.

Examination—I was called by her lawyer to examine her in April, 1902—two years after the injury—at the time of an impending suit for damages. Her condition was as follows. She spoke of her memory being poor and of getting the "blues" easily, though she enjoyed seeing her friends and was generally cheerful. She complained, also, of severe backache and occasional headache, of poor sleep and little appetite. Menstruation was frequent and profuse.

I found her with rather a weak pulse, tremulous lips and tongue and manifestations of a left hemiplegia and left hemianesthesia. The left leg was considerably paralyzed, the left arm was awkward in its movements, but without manifest loss of power. There was impairment of tactile, pain and temperature senses in the left arm and leg as well as loss of smell in the left nostril, and amblyopia of the left eye. The genuineness of these symptoms was demonstrated in the manner already mentioned. The knee-jerks and Achilles tendon reflex were normal.

A few days after this examination the trial was held, resulting in a large award to the patient. The case was appealed and payment was not made until nearly three years later. I had the opportunity to examine the patient several times after this payment was made. The sensory symptoms remained unchanged while the motor paralysis was more marked than at the time of my first visit. My examination on these occasions was a hurried one and no effort was made to test the genuineness of the symptoms.

Sixteen months after the payment had been made while the patient was visiting friends in the east, all her symptoms suddenly disappeared—in answer to prayer, she says. It was a case that was heralded by the papers throughout the land.

I do not think there is any doubt of the influence of litigation in the course of this case.

I wish to add a brief history of a case much like the preceding ones, but in which the question of litigation did not arise.

CASE 4—Mrs. M., aged 66 at the time of the injury. February, 1901, while sweeping the snow from her front steps slipped and fell to the pavement a distance of some half dozen steps. Her daughter picked her up and assisted her to her room on the second floor. Her strength at that time evidently was much greater than it was some days later when as her daughter states, she was practically as I found her nine months subsequently.

1. A physician recently made an examination at my request and found no objective symptoms. The examination was necessarily a cursory one.

Examination—When I examined her she presented a right hemiplegia and hemianesthesia, but the motor paralysis did not affect the face, and the sensory paralysis was not complete, there was impairment rather than loss of sensation, the leg being most profoundly affected. In addition, the patient had much pain in the extremities, which doubtless accounted somewhat for their impaired use.

I had the patient under observation for a number of months during which time there was no improvement in her condition. I saw her again recently, nearly six years after the injury. In the meantime she had very markedly improved. The pains and anesthesia were almost gone, though a trace of the latter remained. The grasp of the right hand was still feeble, and the dorsal extensors of the foot and the flexors and extensors of the toes were paretic.

It may appear from these cases that this disease is found chiefly in females, and, possibly, this is true. But the appearance is accidental in this instance. Of a list of cases I had selected for this paper, cases alike in the type of symptoms and duration of the disease, I was unable to trace the male patients, and do not know their present condition. I was unwilling, therefore, to include them in this report.

The cases I have just reported might be termed traumatic hysteria, though they, also, have a neurasthenic element.² Among the symptoms are the most characteristic stigmata of hysteria, hemianesthesia, contraction of the field of vision, etc. There were also pains of various kinds and local tenderness, as well as symptoms of a neurasthenic type, such as lack of endurance, hypersensitiveness, emotionalism, irritability, depression and self-concentration.

I have given the clinical histories somewhat in detail because they are rather typical of a fair proportion of cases of traumatic neurosis, at least of those of some degree of severity and persistence and which are common subjects of litigation. Naturally other clinical pictures are often presented. Among the cases of the hysterical type, while hemiplegic manifestations are the rule, paraplegia occasionally occurs, or the symptoms may be distinctly localized, or there may be spastic phenomena, such as tremor, contraction and spasm.

In cases of the neurasthenic type we may find any or all of the symptoms common to neurasthenia. Often there are but a few symptoms, localized pains and tenderness, which may be the expression of local injury, and change of disposition, the patient being sensitive, irritable and morbid. Again, there are other cases in which the symptoms are so grave, for instance those of epilepsy or insanity, that we must believe there are profounder changes than those ordinarily found in traumatic neuroses.

DIAGNOSIS

In diagnosis the question that confronts us is not so much whether or not we have a case of traumatic neurosis, for its manifestations are likely to force themselves on us, as whether or not we have, in addition, organic disease of the nervous system. We should always look carefully for all symptoms of the latter, but, no doubt, organic disease is often present when its symptoms elude us. In case of litigation the question naturally arises, have we to do with real diseases or only with simulation?

Simulation is not rare, and yet it appears to be the consensus of opinion among neurologists who have carefully studied the subject that too much has been attributed to it. It is believed that an entire clinical picture such as I have above presented is rarely if ever, simulated while single symptoms possibly may be.

In truth simulation is more likely to occur in those already ill, and, frequently, should be classed rather under exaggeration of symptoms, a phenomenon not rare in the sick, especially in hysteria, and which should not surprise us in this disease in which greed is offered such a tempting bait.

In the report of the first case I mentioned tests which may be applied when the question of simulation arises, and there are other tests for the same purpose. At the same time one must be careful not to be misled by such an examination. For instance, the Mannkopf symptom—acceleration of the pulse on pressing on a point of tenderness—is a positive proof of pain, but, at the same time, painfulness does not always accelerate the pulse.

PATHOLOGY

There has been much discussion of the pathology of traumatic neurosis, but little has been actually established. The older conception, concussion of the spine, and the more common ones to-day, molecular changes and disarrangement of the nerve elements, mean little to us. The intracellular changes found in fatigue, and which may be the basis of hysteria and neurasthenia, as well as of traumatic neurosis, are still far from established in that pathologic relationship. It remains for the future to show whether or not there is some structural change in the nervous system in these cases. Arteriosclerotic changes are not rarely found, but very likely they are the result and not the cause of the disease, sometimes the result of long continued depressing emotions.

The pathogenesis is a more satisfactory subject to treat. Dana's dictum, physical bruising and mental shock, is pointed and, doubtless, correct. Mental shock is the most important factor. Football players and others accustomed to danger, or in a state of mental absorption at the time of injury, appear to be not prone to the disease, though they are not altogether immune. As predisposing factors to the disease a neuropathic disposition stands uppermost. Alcohol sometimes plays a part.

PROGNOSIS

What is the prognosis of traumatic neurosis? Some figures of Putnam throw light on this question. They are based on the study of one hundred cases, with mainly hysterical symptoms, typical anesthetics, etc., in three-fourths of which the patients had instituted claims for damages. From three to twenty years elapsed between the time of injury and the final record of the case. Twenty-five per cent of these patients remained more or less invalided. Sudden recovery was very rare. Knapp gives figures much less favorable than Putnam's. In not more than half of his cases did any improvement take place. In his array of cases the severer types of traumatic neurosis usually followed the severer injuries and vice versa.

The paraplegic type of traumatic hysteria has a less favorable outlook than the hemiplegic. Cases in which there is a marked mental element are also unfavorable, as well as those presenting decided vascular or cardiac changes.

Very frequently, however, the progress is influenced by extraneous elements, such as the environment and, above all, litigation. There are many things connected with litigation that have a decided influence on the patient's mind, such as the frequent examinations of physicians, the solicitous inquiries and advice of friends, the consultations of lawyers, the dread of the court, the desire for a financial award and anxiety as to the outcome,

² Cases 3 and 4 might be classed as simple hysteria.

perhaps a sense of injustice done them that their demand for damages is not readily granted and the like. Such influences tend increasingly to fix the patient's mind on his impaired health and to produce all the ill effects of suggestion, while the natural result of the anxiety and other depressing conditions is steadily to lessen his nervous force and to impair his general health. For all these reasons litigation usually retards the favorable progress of the disease or leads to a change for the worse. It is a common experience that the physician can do little or nothing for his patient until litigation is over, and this is the more unfortunate because prolongation of the course of a nervous case often adds greatly to the difficulties of a cure. Perhaps the strongest proof of the influence of litigation in traumatic neurosis is the fact that in various countries cases of the disease appear to increase according to the success of litigation. The disease has even been attributed to litigation. That the latter is, in general, a false view I need not state. My own interpretation of the apparent proportion of cases to the frequency of litigation is that the latter tends to increase and to prolong the disease in the given case which otherwise would frequently have escaped attention.

TREATMENT

The treatment of traumatic neurosis is, practically, that of hysteria and neurasthenia, and into that subject I need not enter. But I wish to consider some special questions which especially arise in the management of these cases.

In a symposium on traumatic neurosis at the 1900 session of the American Medical Association A. D. Bevan said that the medical attendant, more than any other factor, is responsible for the development and continuance of traumatic neurosis, and claimed that he had nipped such cases in the bud by what he, not inaptly, termed, brutal treatment, telling his patients nothing ailed them, forcibly putting them on their feet and compelling them to walk, and the like. While, in the main, I do not agree with his views, yet there are some practical and important lessons suggested by his severe strictures.

It is generally believed to day that the main element in the production of this nervous disease is mental shock, and as a mental state lights up the disease it is scarcely to be doubted that other mental states have a powerful influence on either increasing and prolonging it on the one hand, or lessening or removing it on the other, hence the immediate and decided effect of the physician and the environment. If the acts and words of the physician and the environment are such as to cheer the patient to inspire him with hope, to make him believe he will soon recover, all nervous symptoms may soon disappear, or at least be favorably influenced. If on the other hand the diagnosis of the physician suggests to him serious disease and in addition, the idea of litigation is thrust on him his symptoms may increase and be indefinitely prolonged.

Let me speak briefly of a patient who has just left my hand—

HISTORY—A man with hysterical antecedents, received an injury to his head evidently a slight one but probably followed by a fright. He fainted and according to his physician's account was thereafter extremely agitated, complained of severe pain in his head and was at times in a state of mental confusion.

He was sent to me ten days after he was hurt with the statement that it was uncertain whether he had serious injury to his brain or not. He complained bitterly when I saw him, and he

had, besides, a degree of left hemiplegia and left hemianesthesia. He stated that the latter, that is, a sense of numbness and weakness in the left side, came on the second or third day after the injury. He had, in the meantime been among anxious relatives and friends. He was immediately removed from all such influences, and his further treatment consisted chiefly of encouragement and suggestion, with the assurance that he would soon be well. Before many days he returned to his home apparently in perfect health. One can scarcely doubt that with suitable cultivation of the symptoms, especially if litigation had been added, chronic invalidism might have ensued in which respect the case is probably typical of much that does occur.

Do not misunderstand me. This was a mild case and, therefore, such a rapid disappearance of symptoms was possible. Had it been a severe one the result might have been different, at least so speedy a recovery could not have been expected.

But, nevertheless, the case serves as a text to my sermon, that the physician should constantly bear in mind the great influence of mental impressions on functional nervous disease, especially in a case of this kind. The physician should aim to remove the patient from depressing environment, particularly from among emotional and anxious friends, he should avoid saying anything unfavorable as to the outcome, but rather should give the most cheerful, hopeful outlook possible, and, above all, he should remember the disastrous effect of litigation and if justice to the patient demands a lawsuit the latter should be kept in the background of the patient's consciousness so far as possible.

I wish to direct attention to only one other measure in treatment, and that is work. Oppenheim's statement that in mild cases work is sometimes curative, but in severe cases the patients should do little or no work, I think must be accepted as true. It would be fortunate, indeed, if when needed, work could more easily be found apportioned to the patient's working capacity. It is often thought that early return to work is a sure means of restoring health. Oppenheim says that too early resumption of work is an unfavorable factor in prognosis.

While writing this paper I saw a woman who suffered rather a severe injury eleven years ago, which was followed by nervous symptoms. Need compelled her to go to work—she is a saleswoman—soon after the injury. She is now suffering much as she did when I saw her nine years ago, and she attributes this to the fact that she had to return to work so soon, an opinion that is probably correct. There are many cases like hers, that is, people who are at work but still sufferers, and who yet are looked on by the world as in good health.

It would be interesting to know of the cases on which Bevan based his opinion of the value of 'brutal treatment,' how many of the patients are really well and how many have been injured by the treatment.

In deciding the question of work we should be guided by the character and needs of the case. In treating functional nervous diseases it is well to be guarded against extreme views such as that rest treatment is always needed or that work is the only cure. A degree of rest is probably always indicated in nervous cases and complete rest in some instances but by no means in all. On the other hand, diversion is usually essential that is something that will take the patient away from morbid thought from self-absorption and from the possibility of auto-suggestion. For the latter reason recreation amusements as work counts especially as resources within him.

ested in other things, and may be especially of value in traumatic neurosis through taking the thoughts away from litigation

In deciding this question in a given case we should judge first of the strength of the patient by observing the effect of exercise on his pulse and breathing, often we shall be influenced by whether work is the one diversion that is effective in his case, and sometimes we are controlled by the patient's financial needs which may compel him to resume work sooner than his condition justifies

Clinical Notes

ACCIDENTAL INOCULATION WITH THE VIRUS OF PLAGUE

PAUL C. FREER, M.D.
Director, Bureau of Science.
MANILA, P. I.

Last fall, as the unfortunate result of the accidental contamination of the cholera vaccine with a culture of plague bacilli, a number of natives were inoculated with plague and several died. The occurrence makes of interest the following account of the work with the cholera vaccine

For the last three years Dr. Richard P. Strong of this bureau has been working on a cholera vaccine which consisted of an extract of the killed, digested and filtered organisms, later modified to a mixture of such an extract with one obtained by shaking on a shaking machine the living organisms in distilled water and then filtering. Obviously this product is always carefully tested and is absolutely sterile and the health department has used on about seven thousand persons in the Philippines. One-half of the prisoners in the government prison at Bilibid were vaccinated with this vaccine and one-half unvaccinated. The same was done in a number of villages in the surrounding territory. Needless to state, no bad results followed from these vaccinations. There is a moderate general reaction following the inoculation, but the local reaction is very slight. The reaction from vaccination with this cholera vaccine is not as serious as that which frequently follows the smallpox vaccination, yet a high blood immunity results.

Subsequent experiments in the town of Angat, where one thousand and seventy-eight persons were vaccinated showed that after vaccination there were one hundred and twenty-two cases of cholera, one hundred and twenty-one of which were among the unvaccinated and only one among the ones vaccinated. In the prison we had no further epidemic of cholera after the vaccination, but no conclusions can be drawn because the cholera was stopped by sanitary measures. It may be stated, however, that since the vaccination we have had twenty cases of cholera, eighteen of which were among the unvaccinated and two among the ones vaccinated.

Dr. Strong continued his work on immunity against cholera by vaccination, as he was convinced that this means was one which would aid in the prevention of large epidemics in the future since it is known that apparently healthy people frequently carry about in their intestines cholera spirilla, which are passed in the stools and hence quarantine and sanitary measures can not always be considered effective safeguards against a cholera epidemic. Certainly the end sought for is a great one and the results satisfactory.

Last year, in a medical congress at Berlin, the method of vaccination by means of the entire organism and not by its extracts was advocated. Haffkine has urged the use of the living organism and believes that by its use a higher immunity can be obtained. Dr. Strong, of necessity to complete his argument, needed to make some vaccinations by this method, as he was convinced it was not superior to the one generally employed by this laboratory, but, obviously, with such arguments in literature, others would come forward attacking his results. In employing the living organism it is necessary to use a 24-hour old culture owing to the fact that after this time changes take place in the culture owing to the formation of ferments, death of a large number of bacteria, etc., and consequently, while the method allows of every test as regards the purity of the cultures up to 24 hours before their use, after this time (when many cultures are employed) no satisfactory test of its purity can be made and no test on animals can be carried on, since the cultures must be inoculated 24 hours after their preparation. Inoculations had been carried on in Bilibid several days without accident. On the day of the misfortune twenty-four men were inoculated, but this was not compulsory. The history of this vaccination is about as follows:

The culture was carefully carried out and identified, and was known to be a pure culture of the cholera organism up to 24 hours before the time when the vaccination was made. A large number of tubes of cholera media were inoculated from these pure cultures and placed in the incubator. On the following morning the cultures were each suspended in one cubic centimeter of saline solution, the whole mixed, and inoculations, as was necessary, made immediately after the preparation of the suspension. It is supposed that some one placed a 48-hour virulent plague culture among the cholera cultures, the blue pencil marks which designated the culture having been erased from the glass by handling. This view is supported by the fact that on the afternoon of the day of inoculation a 48-hour virulent culture was missed from the incubator. It was known certainly that one of the five plague cultures prepared two days previously, as was shown by Dr. Strong's note-book, had been removed from the incubator, but it was not until two days later, when he wished to examine the opsonic index of five guinea-pigs, for each one of which a 48-hour richly-grown culture had been prepared, that the plague culture was missed.

It was proved by a technical committee of three physicians appointed by the governor-general to investigate the matter that a 48-hour richly-grown plague culture spread over the entire surface of the entire slant resembled some of the cholera cultures so strongly that they were unable to identify or to pick out such a plague culture by its gross appearance when it was placed among a number of the cholera cultures of the strain employed. It was also shown that a hanging-drop preparation and the stained microscopic one made from the mixed suspension of all the cholera cultures contaminated with the plague one (as used for the human inoculations) did not reveal the suspicion that the fluid was contaminated with plague bacilli, since no bi-polar staining organisms were visible and evidently, the plague bacilli were in too small numbers or those present did not show any sufficiently distinctive morphology to separate them from the pleomorphic cholera organisms in the saline solution. Nevertheless, this same suspension, in which plague bacilli were not detected by microscopic

examination, when injected subcutaneously into guinea-pigs and a monkey, caused, after several days, death from plague infection. It has not been ascertained who placed the plague culture among the cholera ones after all possible tests of the cholera culture had been made. An investigation of the entire matter was pursued by the government prosecuting attorney at our request, and later the governor-general, in order to satisfy public opinion, appointed a committee of eight, six Filipinos, one American and one Englishman, three of which committee constituted a technical committee, for investigation.

While the serum division of this laboratory is also in charge of Dr. Strong, and while this division prepares our regular cholera vaccine, it must be clearly understood that the regular preparation of our cholera prophylactic had absolutely no connection with this matter and that the vaccine used by Dr. Strong on the day of the accident is entirely distinct from the preparation with which he is identified. The method used on the last twenty-four prisoners is the one which is best known by the names of "Ferran" and "Haffkine." It is perhaps unnecessary to add that the laboratory has prepared several million units of vaccine virus and several thousand doses of plague prophylactic which have been used (in addition to the cholera prophylactic) with good results and without accident.

A NEW NASAL DRESSING

JAY G. ROBERTS, M.D.
OSKALOOSA, IOWA.

I think it will be generally admitted that the ordinary methods of packing the nasal cavities after operation are unsatisfactory. Packing with gauze is particularly so. It is difficult by this method to secure sufficient pressure in the proper place to control hemorrhage efficiently. By its capillarity the gauze acts as a drain, keeping up a continual oozing, which may even reach alarming proportions. It is continually getting down into the pharynx causing retching and tempting the patient to remove it. Its removal is painful, interferes with healing and always occasions more or less secondary hemorrhage. The open method, with or without the application of collodion to the surfaces operated on, is dangerous and not to be considered as a routine measure.

The Simpson tampon of compressed absorbent cotton in various sizes is a fairly satisfactory dressing but for the difficulty attendant on its introduction or removal. It bends, swells rapidly on contact with the secretions of the nose, making it difficult to introduce and place properly. It clings to the injured surface most tenaciously, causing severe pain and making its removal in the mass practically impossible. When removed piecemeal shreds of considerable size are left adherent to the wounded surfaces and hidden away in nooks and crannies where it is almost impossible to distinguish them from the wound surfaces when they are stained with wound secretion. Unless discovered and removed they keep up a constant irritation, prolong the healing process and contribute to the chances of infection.

To overcome these objectionable features I use the following method which it seems to me solves the problem of nasal packing after most operations.

From a piece of sheet paraffin or dental wax as it is called two splints are cut, conforming in shape to the Simpson nasal tampon and about 15 mm (5/8 in.) longer than the tampon and a piece is cut from a second

tampon to fill in the extra length. The tampon is now placed between the two strips of paraffin, to which it is cemented by means of aristol-collodion. Any thickness desired may be had by varying the thickness of the Simpson tampon, either by splitting them or by using the different thicknesses in which they come. The completed tampon is now pushed into place a procedure which is facilitated by the smooth waxy surfaces of the splints. Once in position the cotton rapidly absorbs moisture from the adjacent mucous membrane and, swelling, forces the paraffin plates against the septum and the outer wall of the nasal cavity. Under the influence of the body temperature the paraffin becomes pliable and is thus molded into accurate apposition with the wound surfaces, controlling hemorrhage and making an ideal non-irritating, protective dressing. When the time comes for its removal, which should be at the end of 48 hours the tampon can be removed *en masse* easily and painlessly, there being absolutely no adhesion between the paraffin plates and the wound surfaces. Their greasy smooth surfaces offer no resistance to removal and they slip out without pain, hemorrhage or other inconvenience.

A spur or ridge of the septum may be removed coincident with the removal of a turbinate, without the slightest danger of synechia, if this dressing is used and a single plate of the paraffin replaced after the removal of the tampon and worn until healing is complete.

In submucous resection of the septum it is an excellent dressing. Using a tampon in each nostril, any degree of firm equable pressure may be obtained and maintained as long as desirable and they may be changed as often as desired without disturbance of the parts.

By placing the Simpson tampons in a letter press or between heavy weights to prevent their expanding they may be impregnated with alcoholic solutions of aristol, iodoform or other antiseptics and allowed to dry before being placed between the paraffin plates which also may be kept in an antiseptic solution thus making an antiseptic as well as aseptic dressing.

A METHOD FOR THE RAPID DIAGNOSIS OF DIPHTHERIA BY THE GENERAL PRACTITIONER*

FRANK M. WOOD, A.B., M.D.
CARLEVILLE, ILL.

The necessity for the early diagnosis of diphtheria is often painfully apparent to the general practitioner as failure in that regard too often results in involvement of the larynx especially in children while this in turn frequently ends in the early demise of the child. I therefore offer this method to the profession with the hope that it may facilitate the diagnosis of this disease.

It is necessary first to obtain a culture from the throat or nose of the patient by means of a swab of absorbent cotton or the platinum needle. A swab which is very convenient for this purpose may be made as follows. An ordinary test tube is sterilized in the Pinner or alcohol flame. A wire is bent with a loop at both ends and made just long enough to fit the tube. One end of this wire is then wound with wire and twisted in the form of a convenient sized swab the other end is wound with similar wire twisted so as to fit the top of the tube and a stopper similar to the cotton stopper of the ordinary culture tube. The whole assembly is then sterilized in the flame and placed within the tube and is then ready for use. The

* Read before the Academy of Medicine, Chicago, 1907.

tube may be carried in the overcoat pocket and used in any suspected case. Its chief advantage is that it may be used repeatedly, sterilizing it each time in a flame. I am indebted to Dr. Wright of the staff of the Calumet and Hecla Mining Company's Hospital for this method of preparing a universal swab, and wish to pass it on to others for what it is worth.

The next step in the process is to obtain some Loeffler's blood serum tube slants, these can be obtained from any of the reputable pharmaceutical houses and may be kept on hand for a reasonable length of time without contamination. They may be kept at the office or one may be carried in the pocket, as necessity demands.

The swab is rubbed over the suspected area of nasal mucous membrane, or tonsil or pharynx, and a smear made at once on an ordinary cover glass or glass slide. The serum slant is inoculated by passing the swab gently over its surface, and the swab is then sterilized in a blue flame and replaced in its tube for future use.

The inoculated serum tube must be incubated for 12 hours, this can be easily done in the following manner. The tube is slipped in the inside vest pocket and kept next the body for twelve hours, the physician acting as his own incubator. At the expiration of that length of time if the diphtheria bacillus be present there will appear a yellowish white glazy growth,

The practitioner may also keep a check on his diagnosis by sending specimens to the state laboratory for diagnosis.

IMPROVED FRACTURE APPARATUS

CHARLES H. LEMON, M.D.

MILWAUKEE, WIS.

The apparatus here shown is the result of combined effort on the part of Dr. Frederick T. Mueller of Chicago and myself, with the assistance of Mr. S. George Hubbell of Milwaukee, a mechanical expert, who carried our ideas into effect. The purpose of the machine is to enable the surgeon to reduce a fracture of any of the long bones of the lower extremity and hold the fractured ends in apposition while a permanent set is made by a plaster cast. It is used also in various orthopedic operations.

To facilitate the reduction of fractures the patient is placed in a horizontal position on the machine, the feet being separately fastened to the foot rests on the ends of

with white colonies here and there, showing irregular edges and smooth surfaces. Smears from this culture are examined microscopically, the staining being done with Loeffler's alkaline methylene blue stain. If the characteristic bacilli with their long beaded threads, clubbed ends and irregular sized dots are found the clinical diagnosis of diphtheria is corroborated.

McFarland says: "Very few other germs found in the throat will produce so rapid a growth on this culture media." This I have found to be true, perhaps with one exception, and that is some varieties of the streptococcus, these, however, may be differentiated by the characteristic dew-drop appearance of the culture on the serum slant when it first appears, and the chain-like structure of the coccus under the microscope. While waiting for the growth to develop the smears made directly from the throat may be examined microscopically and if suspicious bacilli are found it will help to confirm the diagnosis.

The advantages of this method are the necessity of waiting from 24 to 48 hours or even more is obviated.

The general practitioner becomes expert in identification of the diphtheria bacillus.

the long rods, the sacrum resting on the horizontal plate supported on the vertical post, which latter comes between the legs and touches the pubic arch. The shoulders of the patient rest on the support at the free end of the main frame, which is attached to the table, while the head rests on a box or on pillows placed on the table.

The two upright supports seen on the horizontal rods are to support on one side the sound knee and on the other the site of fracture so as to prevent backward bowing, the extremities being kept in even planes. In order to facilitate adjustment of fragments and to overcome distortion of proximal fragments such as occur in fractures of the upper third of the femur, the two long rods may be adjusted to any angle the human leg can be placed in. These rods are attached by their proximal ends to the main frame of the apparatus by friction-disks, which permit of universal joint movement.

The extension of the legs is made by screws attached to the hand wheels seen on the foot brackets. These screws pull the body toward the foot rests until the pubic bone impinges firmly against the vertical post in front of the horizontal plate on which the sacrum rests. Ad-

ditional extension can be made on either leg as desired until the bones are accurately adjusted. It will be seen that no movement of the fragments is possible after being once adjusted until the screw pressure is released.

The plate for supporting the site of the fracture may be tilted by means of a hub on the fixture so that in supracondylar fractures of the femur relaxation of the gastrocnemius muscle may be effected and the leg brought to the double inclined plane position by elevating the supporting plate by means of the small hand wheel which turns on the threaded vertical portion. The horizontal rods may be raised or lowered from the horizontal plane and abducted or adducted, or these movements may be combined. The foot brackets slide on the horizontal rods so that the machine is quickly adjusted to fit a large or small person.

These machines are manufactured by The Badger Appliance Company of Milwaukee, Wis.

HOLES IN THE MESENTERY WITH HERNIATION OF THE INTESTINE

G. K. DICKINSON, M.D.
JERSEY CITY, N. J.

These anatomic curiosities, due to defect of development or subsequent alteration in structure, seem to attract little attention, nevertheless, they are of scientific interest. Holes in the mesentery are apparently of great infrequency and with few exceptions no references to them are found in the literature nor attempts to explain their origin. In the mesogastrium (the omentum) they are not infrequent. It is probable that the same conditions which cause them in the omentum lead to their formation in the mesentery. They are seldom found in the upper part, the nearer the cecum the more numerous and the larger they become. Traumatism with laceration, the breaking down of caseous glands, and emptying of serous or chylous cysts may give origin to them, but the most frequent situation for their location being proximal to the cecum, suggests defective arterial supply and gradual absorption as the more logical explanation for their existence. Anastomosis of the ileocolic branch of the mesenteric artery, with the intestinal branches, is sometimes so incomplete that it is often impossible to inject this area. These holes in the mesentery, when due to laceration, are jagged and irregular, but when due to gradual absorption of the constituents of the tissue the edges are even rounded and not cicatricial. Through these foramina herniations of gut may occur causing strangulation.

CASE 1—J. D., a railroad hand aged about 45, was seen at the Bayonne Hospital through the courtesy of Drs. Sexsmith and Abbott.

History—The man had been ill three days with symptoms of appendicitis, temperature was 102 F, pulse over 100. There was general abdominal tenderness focusing at the cecum, the abdomen was hard and tympanitic. The man vomited contents of the stomach and upper intestine. The general condition was bad.

Operation—An incision was made through the sheath of the right rectus. General peritonitis was present as evidenced by seropus and flakes of lymph between the intestinal coils. In the cecal region a hole was discovered in the mesentery at the terminal end of the ileum, close to the cecum with smooth margins and regular outline about two inches in diameter. Through this, from above, passed a coil of small intestine for a distance of over two inches. It was not adherent to the margins of the hole but was held in place by the tip of an ascending gangrenous appendix. In other words there was

intraperitoneal herniation of a knuckle of gut through the hole, the herniated portion being held in position by agglutination to the tip of the appendix, the appendicitis was subsequent to the former condition.

CASE 2—E. E., aged 10, entered Christ Hospital, Jersey City, Jan. 5, 1907, and was seen through the courtesy of Dr. Franklin.

History—For five days the patient had had obstipation with tympany, but no rise in temperature. There had also been colic and green vomit. The condition was bad. Examination proved negative.

Operation—The abdomen was opened through the sheath of the right rectus. There was a considerable quantity of intraperitoneal fluid. The coils of small intestine were much injected and roughened but there was no lymph deposit. Meckel's diverticulum was pear shaped, with a two inch pedicle, three eighths of an inch in diameter and very firm, there was also a cyst like enlargement at the periphery one and one half inches in length. The diverticulum looped over and herniated through a small hole one-quarter of an inch in diameter, in the base of its own mesentery, on a direct line with its origin. The cyst like expansion protruded on the side distal to the loop and was anchored by its enlargement. Through this loop several inches of small intestine were herniated proximal to the origin of the diverticulum. The hole in the mesentery was stretched by artery forceps, the diverticulum was withdrawn and, including the loop of intestine, liberated.

SOME OBSTETRIC EXPERIENCES IN CHINA

W. H. VENABLE, M.D.

Formerly of the Sloane Maternity Hospital New York City
KASHING, CHINA.

There is no way of estimating the mortality from childbirth in China, but it must be very large. Ignorant midwives attend most of the cases. A physician is rarely sent for, and when he comes so far as I can learn, he is not supposed to examine the patient but merely feels her pulse and writes a prescription for the particular complication from which she is suffering. A woman in labor is considered unclean, and ordinarily a Chinese doctor would not be willing to pollute himself by coming in contact with the discharges from a labor case. Among the higher classes, especially the relatives of a puerperal woman will not come into her room until a month after her delivery. She is taken care of by midwives and female servants. The result of such neglect can easily be imagined.

PLACENTA PRÆVIA

One of the first obstetric cases I saw after coming to China was a case of placenta prævia at about the sixth month. The patient had been having pains for several days and on examination I found the os dilated to two inches in diameter and the placenta presenting. Miscarriage was apparently inevitable. At that time I had no hospital or room of any kind in which I could put an inpatient. As the woman had come from a distance I advised her to rent a room near by and let me attend her. As she was suffering a good deal of pain I gave her a hypodermic injection of morphin and then she and her husband got on their boat, he promising to come for me as soon as he succeeded in renting a room. I did not see them again for two days when they both appeared at the dispensary and informed me that the miscarriage had taken place healthily after she got on the boat. The woman said she was feeling all right and they insisted on going back home. She was loud in their praises of my skill (as the morphin had relieved her pain almost immediately and as he thought he had brought on labor which was painless). At the time I saw her there was very little hemorrhage though as I reflected he gave the history of having had severe hemorrhaging some time before I saw her. This woman made a good recovery though after she returned home she had an attack of fever which they said was malaria.

TRANSVERSE PRESENTATION

Another one of my earliest cases was a transverse presentation with prolapse of the arm. After a good deal of manipulation I succeeded in pushing up the arm and changing the position to a vertex. Then I applied the ordinary McLane forceps at the superior strait and delivered without any particular difficulty. The child was a large, healthy boy. The woman appeared to have an irregularly shaped, though not contracted pelvis. She gave the history of having borne one child previously, which also presented transversely, the attending midwife had delivered the child in sections, probably beginning by pulling off the arm. The woman has not borne any children since.

ECLAMPSIA

One morning early I was called to see a patient who had been brought to the door on a boat. She was in a deep stupor and could not be aroused. It was evidently a case of eclampsia. Labor pains had ceased and the os was dilated enough to admit two fingers. The patient's friends and family were extremely anxious for her to be delivered as quickly as possible, even if the child had to be mutilated. That is, they insisted that I act in the interest of the woman, without regard to the child. The patient was a primipara and the child seemed to be large, so I felt that haste was necessary if the woman's life was to be saved. After dilating the cervix as much as I could with my fingers I reluctantly proceeded to do a craniotomy. As soon as the child was delivered, the people said that they had to go. I urged them to stay and let me do what I could for the woman, who was still in a stupor, but they insisted on leaving, as they had hired out their boat for a trip that day and would lose the money if they did not appear on time. I managed to pour a large dose of magnesium sulphate down the woman's throat at the imminent risk of strangling her, and then they left. Some days afterward they came back and reported that the woman was entirely well, and they seemed very grateful for what I had done.

Some months after this I was called to see another case of eclampsia, this time in a multipara. This woman also was in a deep stupor. Labor had not begun but as she had a oomy vagina and pelvis, I found no particular difficulty in performing manual dilatation of the os and delivering immediately with forceps. The child was alive and healthy, but, in spite of all I could do, the mother continued in her unconscious condition and finally died.

CRANIOTOMY

One day I was called to see a case of difficult labor several miles out in the country. As the messenger who came for me said that the child's head was visible I did not take my craniotomy instruments with me. When I reached the patient I found a case of contracted pelvis with the child's head above the brim. The fetal heart was very slow and barely audible. What they had taken to be the child's head I do not know, unless it was the swollen and discolored external genitals or possibly a blood clot. I was in a quandary. However, after soaking my penknife in a carbolic solution for a while I succeeded in perforating the head with it. Then by using my McLane forceps as a cranioclast, I reduced the size of the head enough to accomplish the delivery. The patient made an uneventful recovery, and I have seen her a number of times since.

PODALIC VERSION

A little over two years ago I was called to see the most difficult obstetric case that I have ever been my lot to attend. The patient lived about 2 miles out in the country. I was called at night and my Chinese assistant and I went in a boat. We found the patient in a straw thatched hovel with a dirt floor, lying in a dark corner on a pile of straw. It was a transverse presentation and the child's arm had been broken by the midwife's efforts at delivery. The patient was in an exhausted condition, her lips were parched and dry and her pulse was 120. The doubled up chest of the child was jammed down into the pelvis and the arm was prolapsed. The uterus was contracted so firmly on the rest of the child's body that it was impossible to push the prolapsed arm or the chest up above the brim. I had no bore forceps with which to cut the ribs and cause the chest

to collapse, so the alternatives left to me seemed to be decapitation and podalic version, both of them about as difficult and dangerous under the circumstances as one could well imagine. I have never had any leaning toward decapitation. The thought of a trunkless head inside of a firmly contracted uterus is not, to my mind, a particularly enviable condition to treat. Podalic version, if it were possible, seemed to offer the best chances of a quick delivery, which was the great desideratum, considering the condition of the patient. I decided that the danger of rupturing the uterus or otherwise injuring the soft parts by manipulation was more than overbalanced by the greater danger of leaving the woman undelivered, so I determined to use a good deal of force, if necessary. To get my hand and arm past the child's doubled up chest as it lay in the pelvis seemed a physical impossibility, and so I thought it was going to be when I first tried it. Gradually, however, I worked my arm up in spite of the great pressure until my fingers came in contact with the child's feet. When I tried to grasp a foot I found that I could not, as my fingers were numb from the pressure. I tried again and again without the slightest success. As the numbness was increasing, there was nothing to do but to withdraw my arm. After waiting a while, I tried again. About this time my assistant informed me that the patient's pulse had increased to 140, so feeling that I must not lose any time, I made a desperate effort and succeeded in grasping a foot firmly enough to exert a little traction. Then I got a better hold and exerted more traction, and as a result the mass that had seemed hopelessly wedged in the pelvis began to move upward. It was not long before I had a foot out, and of course the rest was easy. I was surprised at the marked effect of moderate traction on the foot in making the impacted chest go back into the uterus, in spite of the fact that the uterus was in a state of tonic contraction. This patient also made an uneventful recovery.

DELIVERY OF MORIBUND PATIENT

A little more than a year ago I saw a case of twins that illustrates the influence of Chinese superstition on foreign medical practice. One child had been born the day before I was called and was living. The second child, much the larger of the two, was still in the uterus. It was evident from the degree of maceration and the odor that the child had been dead for some time. As the mother was almost moribund, I told them that I did not care to undertake the case. I told them that the patient would probably die during delivery or soon after. They replied that they realized the woman's desperate condition, but that they wanted her delivered, living or dead. Their extreme anxiety to have her delivered was due to a belief of the Chinese that a pregnant woman who dies undelivered is doomed to continue carrying the child in the next world. After receiving their assurance that I would be free from responsibility for the death of the woman, I proceeded to remove the putrid fetus. Labor pains had ceased entirely and the breech was presenting. On account of the large size of the fetal head and the rigidity of the maternal tissues, I had to apply forceps to the after coming head. The patient died a few hours after delivery.

UTERINE INERTIA.

Chinese women seem to be subject to uterine inertia. It is not surprising that this should be the case in women of the higher classes who have bound feet and who take practically no exercise but I have been struck with its frequency even in hard working women with natural feet. Often after the os is half dilated the pains become feeble and ineffectual and the labor drags on hour after hour, making scarcely any progress. Making these patients walk around or giving them quinin seems to have very little effect. In a great many cases, however, rupturing the membranes early (i. e., when the os is about half dilated) seems to have a remarkable effect in stimulating the pains. I have done this so often lately and with such uniformly good results that the conviction is constantly being strengthened in my mind that after the os is dilated to about two inches in diameter, the "bag of waters" rarely serves any useful purpose and often makes the pains ineffectual.

Recently I attended a multipara with marked uterine inertia. The os was dilated to about two inches and she seemed

to be making no progress. The pains were very feeble and seemed to have scarcely any effect on the dilatation. I ruptured the membranes, and the pains increased enough to dilate the os to about three inches, and then there was no further progress. The pelvis was roomy, the child's head was small and there was no rigidity of the cervix, but still the head refused to descend. I applied the forceps and, though the traction used was very slight, the head came down without the least difficulty and delivery was soon accomplished. I think I have never used such a small amount of traction in a forceps delivery.

Though my obstetric practice is not large there is a steady increase, which shows that the Chinese here are beginning to realize the value of foreign methods in this branch of medicine. In looking over my records I find that in about ten years of hospital work here there have been 14 forceps deliveries, 4 craniotomies, 2 transverse presentations, 1 cephalic version, 1 podalic version and 1 premature labor for hyperemesis gravidarum.

During 1906 I had 12 cases, more than in any previous year. Several were in wealthy, influential families.

China is making rapid strides toward civilization, and Western medical science is destined to be an important factor in the process. A large number of medical books have been translated into Chinese by medical missionaries and more are constantly being translated. There are several medical schools in China and we hope to see a medical magazine in Chinese established at no very distant date.

LIGATION OF THE BLEEDING VESSEL IN THE HEMORRHAGE FROM DUODENAL ULCER

R. R. HUGGINS, M.D.
PITTSBURG, PA.

In view of the present diversity of opinion concerning the advisability of direct ligation of the bleeding vessel in ulcer of the stomach and duodenum, the following case is reported.

Patient—Mrs. F., aged 26, was seen in consultation with Dr. W. N. Humphrey, Oct. 8, 1906.

History—She had been married eleven years and had had one miscarriage at third month, no children. Her general health was good until three years ago, when pain began in the right side of the chest radiating to the back. It was more or less constant and always greater after eating. Some foods caused more distress than others. There was vomiting at irregular intervals, and she was usually worse before the menstrual periods. The patient never vomited blood until Oct. 2, 1906, when a very severe hemorrhage occurred. This was quickly followed by a second and third attack on the same day. On October 3 another severe hemorrhage occurred and a large quantity of blood was passed from the bowels. After this bleeding from the stomach occurred until October 5, when the blood continued to be present in the bowels. During this interval in the afternoon of October 4 another hemorrhage occurred. At this time I was called and found the patient in a condition to be critical, as denoted by a very pale, anemic, and pallor. All treatment, medicinal and surgical, being administered without any effect on the hemorrhage, it was advised. Early the following morning she was removed to the hospital, another hemorrhage occurring before her removal. In such a serious condition that the emergency was to convey her to the hospital. The patient's condition on admission was one seen in cases of extreme anemic. Her weak and rapid extremities and other symptoms indicated. The continuation of medical treatment was advised. For the following twenty-four hours the patient was treated and given injections of normal saline. At the end of this time her condition was such that it was decided to view of the possibility of permanent relief, the location of the bleeding vessel being determined by the following method.

Operation—On October 10, under light ether anesthesia administered by Dr. Stuart, an incision was made in the median line. Careful examination of the external surface of the stomach and duodenum failed to reveal the location of the ulcer. The stomach was then opened by an incision through the anterior wall at the pyloric end. An ulcer was found in the duodenum just below the pyloric ring. It was of the mucous variety and was situated so close to the ring that external palpation did not reveal its location. The ulcer was transfixed and ligated with catgut and the peritoneal surface reinforced by mattress sutures. The opening into the stomach was closed and a posterior gastroenterostomy with no loop was performed. It was necessary to administer considerable stimulation throughout the operation, but the patient rallied well and made a good recovery. There has been no further hemorrhage and she is now free from pain and eats everything without distress.

The diagnosis as to the definite location of the ulcer was uncertain. While large quantities of blood coming through the bowel and the peculiar location of pain seemed to point to an ulcer of the duodenum, yet it seemed somewhat doubtful that such large quantities of fresh blood would pass backward so quickly into the stomach. It was evident, however, that it was located near the pylorus. The indications for treatment remained the same in either case.

A CONVENIENT METHOD OF OBTAINING CLUMP-FREE EMULSION FOR OP- SONIC WORK

J. E. POTTENGER, M.D.
MONROVIA, CAL.

While studying the specificity of opsonins last summer in Professor Wright's laboratory I sought for a method of quickly separating organisms from the liquid in which they are suspended, centrifuging alone requiring from thirty minutes to one hour. The following device was used with splendid success. A constriction (A) is made in a piece of small-caliber glass tubing the tubing is then bent on itself (B), terminating in an opening (C). Moist filter paper fiber (D) (conveniently made by scraping filter paper with the edge of a knife) is placed against the constriction and packed firmly. Into the long arm is placed the liquid (E) to be filtered and the device is placed in the centrifuge.

Working with staphylococci, I obtained practically bacteria-free filtrate (F) in ten to fifteen minutes from thick suspensions of staphylococci in normal sera. The filtrates showed scarcely any opsonin, and stained specimens practically no organisms. Similar rapid ugo-filtration of tubercle bacilli required but a few minutes, since the fiber need not be packed so tightly. The device, however, has a more practical application. When a bacterial emulsion presents resistance to ordinary mechanical means of separation, a clump-free filtrate may be obtained by the use of a few opsonic work in twenty or thirty minutes. If the filtrate contains clumps it is easily removed by introducing a capillary pipette into the filtrate so that repeated filtration can be accomplished. This method is more certain than the use of a centrifuge, and is likely to be too thin. The device is accomplished in a few minutes.

AN IMPROVED TRACTION SHOE

JOHN JOSEPH NUTT, B.L., M.D.

Clinical Instructor in Orthopedic Surgery, Cornell University Medical College Assistant Surgeon to the New York State Hospital for Crippled and Deformed Children
NEW YORK CITY

The successful treatment of Shaffer's foot, invariably, and of flatfoot, frequently, depends on the elongation of the gastrocnemius muscle. Compensation in the former condition, by means of a higher heeled shoe, and splinting the deformed foot with steel arches, in the latter condition, are measures which generally give relief, but of themselves are not curative.

An active foot, with limitation of dorsal flexion, must suffer from the alteration of its mechanics. The changed disposition of the superincumbent weight and the abnormal points of resistance due to the restricted movements of the lever-arms, must, inevitably, cause such disturbances as result from pressure, i. e., corns, bunions, callosities, "ingrowing toe-nails" and Morton's toe and an alteration, or a tendency to an alteration, in the relations of the tarsal bones. Whether the foot becomes what is known as flat, or presents a higher arch than formerly, depends on the amount of limitation of dorsal flexion and on the strength of the plantar tissues which serve to maintain the normal medio-tarsal joint.

Figure 1.

Every examination of an extremity should include an examination of all its joints. Examination of the ankle joint will often determine the cause of a thigh, leg or knee pain which, erroneously, has been considered rheumatic, neuralgic or neuritic. A painful flatfoot having a shortened gastrocnemius may often be relieved by restoring normal movement to the ankle joint, even without any further attempt at restoring the arch. When a neglected Shaffer's foot has resulted in a flatfoot an artificial arch alone can not be expected to cure. The prolonged use of steel arches is seldom necessary and must be productive of atrophy of the small muscles, ligaments and fasciæ of the foot.

The apparatus in general use for stretching the post-tibial muscles is the traction shoe devised by Dr. Shaffer and presented to the profession about twenty-five years ago. With this machine any desired force can be applied. From a therapeutic standpoint it is unqualifiedly successful. The force is the resultant of two forces, one applied in an antero-posterior direction through a strap passing behind the heel and called the heel-strap, and the other a force applied through a strap passing over the neck of the astragalus and called the astragalar

strap. This resultant pulls the calcaneum downward and forward in an arch whose radii are from a center passing through the astragalus just below the external malleolus, the transverse axis of the ankle joint. In very resistant cases, however, the force exerted by the astragalar strap is such as to cause considerable discomfort.

In the apparatus presented herewith the astragalar strap is not brought into use until the gastrocnemius is well stretched, and then a momentary hyperextension is obtained by the use of an antero-posterior ratchet exactly similar to the one in Shaffer's shoe.

The machine consists of two lateral bars, a stand and a foot-piece. The lateral bars A, A, are joined at their distal ends in a U shape piece. Their proximal ends are bent so as to pass beneath the chair, where they are secured by a draw-pin which passes through a socket

Figure 2.

screwed to the bottom of the chair-seat. The continuity of these lateral bars is interrupted just below the calf-band M, and the ends, overlapping, are held by thumb screws. Thus these bars may be shortened or lengthened as desired. The stand B, B supports the machine. It is detachable. The foot-piece consists of a foot-plate C and a heel-cup D. The foot-plate is joined to the heel-cup through the ratchet bar G, passing through the sheath E, which is secured to the bottom of the heel-cup. The entire foot-piece is riveted to the lateral bars at J, J, and by means of the ratchet F can be moved about the axis passing through J, J. The arc of the ratchet F is constructed on the radius JF.

To the bottom of the foot-plate are riveted two buckles h, h which secure the heel-strap. This strap passes behind the heel, forward on both sides of the foot over the hangers i, i, projecting upward from the front of the foot-plate and backward to the buckles. On each side of the heel-cup are pulleys, k, k through which the astragalar S is roven. The strap crosses over the ankle opposite the head of the astragalus, from one pulley to the other and is doubled back and one end passed through the buckle sewed to the other end.

The method of application is as follows. The patient is seated in the chair, the heel placed in the heel-cup D, and the lateral bars A, A are adjusted by means of the thumb screws to the exact length of the limb with the leg fully extended. It is necessary that the axis of the ankle joint should pass through the axis of rotation of the foot-piece J, J. The heel-strap assists greatly in obtaining the alignment of these two axes. While fitting the apparatus the foot-piece should be plantar flexed to an angle affording an easy position for the foot. The last thing to be done is to fasten the strap of the calf band. This prevents the patient flexing the knee as the strain comes on the gastrocnemius.

Traction may now be started. Using the key f, the ratchet F is made to pass forward and around the axis J, J. Everything on that foot-piece will move through arcs whose radii extend from the common center. The foot is thus moved forcibly, about the ankle joint. When the tautness of the tendo-Achilles, as ascertained by palpation and the sensation of the patient, warns one that full flexion is obtained, the astragalar strap is applied and a momentary hyperextension produced by means of the antero-posterior ratchet G. Those familiar with Shaffer's traction shoe will recognize in this part of the treatment the copy of that shoe. Furthermore, it should be mentioned that Dr. Shaffer, by means of a worm and screw, also altered the angle of flexion and extension of the foot-piece.

A NEW PRINCIPLE IN IRRIGATION OF THE URETHRA WITH INSTRUMENT

J. H. BACON, B.S., M.D.
PEORIA, ILL.

I have been using a new principle in the treatment of gonorrhea, and the results seem to me to be good. The difference between my method of treating gonorrhea and that of those who use irrigations is not medicinal but mechanical. Instead of using only the force of pressure from gravity for irrigation of the urethra, I have added a bulb to the irrigation tube, and by intermittent pressing obtain an intermittent or rather a rhythmic pressure. The value of this kind of pressure over simple pressure was brought to my mind by seeing the blood vessels pulsate in the thigh of one of my patients while I was irrigating and remembering that the blood will not continue to circulate if the pressure is steady. It is only when the pressure is rhythmic that the blood will pass through the capillaries. Now if we use Nature's method we must use rhythmic pressure in irrigating if we wish to have the fluid penetrate deeply into the lining membrane of the cavity irrigated. If the urethra were a flat surface the treatment would be simple and cleanliness could easily be maintained but being an elastic tube it is more difficult to give it the very essential cleaning.

I use a quart glass fountain that can be raised or lowered at will. At the bottom it is connected with six feet of rubber tubing. Into this tubing about one foot and a half from the distal end is fitted a valveless rubber bulb the size of an atomizer bulb. A long blunt glass nozzle is attached to the distal end of the tube over which a half of a hollow rubber ball is placed in such a manner as to protect the hands of the operator from escaping fluid returning from the urethra. The bulb is used without valves so that the pressure used can not rise much above the fountain head without being

regurgitated into the fountain. This protects the bladder from being invaded if the fountain is not raised more than two to two and one-half feet above the level of the urethra. All the apparatus can be readily and cheaply set up in the office, and yet be efficient.

When a patient presents himself in the early stage with a thick discharge showing the intracellular diplococci he is instructed to keep the bowels loose, drink freely of water, abstain from alcohol, coffee and spiced food, avoid excesses of all kinds and get abundance of sleep. Internally he is put on 15 grains of hexamethylenamine and 3 minims of oil of sandalwood three times a day. Sometimes I have given Lafavette's mixture in conjunction, with hexamethylenamine with good results. The urethra is irrigated four times a day with warm normal salt solution for the first week. The irrigating fluid is changed to 1 5000 potassium permanganate the second week and 1 1000 silver nitrate the third week and this continued till cure is established. I hold the case cured if after one week's intermission no gonococci are found.

The irrigating fluid is heated to about 125 degrees Fahrenheit the fountain maintained at two feet above the level of the urethra and the meatus and first half inch of canal washed out after the patient has urinated. The nozzle is then more firmly pressed into the urethra and the bulb pressed quickly and softly at the rate of about 80 to 90 to the minute. The urethra is seen to pulsate with each compression of the bulb at the same time there is some escape of fluid around the nozzle. The fluid penetrates deeply into the follicles and glands of the mucosa the nidus of the infection and one can often see little yellowish white specks of pus that are jarred loose and swept out in this pulsating stream of fluid which would have remained in place for days and maintained the infection. In my experience the duration of an infection can be shortened from one to two weeks. This same principle of rhythmic pressure can be used with advantage I believe in the rectum and colon, the pericardium or

THE RELATION OF CHLORIDS TO EDEMA

Although several writers had previously suggested the possibility of edema being due, at least in certain conditions, to the presence of abnormal quantities of sodium chlorid in the tissues, yet general attention was first called to this possibility by the observations and writings of H. Strauss in Germany and of Widal in France in 1902 and 1903. These clinicians observed a striking correlation between the elimination of chlorids and the development of dropsy in certain cases of nephritis, and brought forward evidence to support the hypothesis that in nephritis the ability of the kidney to excrete sodium chlorid is decreased, and that the retention of this salt in the body causes a corresponding retention of water to dilute the salt to that degree of concentration which is compatible with the normal osmotic pressure of the blood and tissue fluids. Many clinicians adopted the suggestions of Strauss and Widal as to the treatment of edema by reduction of the chlorids in the food, and soon the literature of all countries was filled with reports on this subject, describing results and giving conclusions greatly at variance with each other. The first excitement having passed, it is now safe to analyze the various reports that thus far have been submitted, and to attempt to draw conclusions with some hope that they may be reasonably correct.¹

In the first place, the reports of many competent observers leave us no choice but to conclude that in nephritis, particularly of the parenchymatous type, retention of chlorids often occurs, yet in some typical cases with edema it may not be possible to demonstrate such retention. Also, patients may show a distinct chlorid retention for some time, and then, without evident reason, the retention may cease. Furthermore, in some cases of interstitial nephritis retention may be as marked as in the parenchymatous forms, and this retention is not always associated with edema. In certain cases of nephritis, the edema will be found to vary directly with the degree of chlorid retention, as in the striking instance reported by Widal and Javal, in which it was possible to cause the edema to appear and disappear almost at will by varying the amount of the chlorids in the diet. In other cases, however, even the most careful reduction

of the chlorid intake will not appreciably modify the edema, while in perhaps the largest number of cases the amount of edema may be reduced by this means, but not always strikingly or constantly. In other words, the weight of evidence indicates that retention of chlorids frequently is an important feature in the edema of nephritis, but it is not always possible to demonstrate its relation to the edema. Apparently the power of the kidneys to eliminate chlorids varies from time to time, just as the excretion of albumin and the presence of casts may vary. Probably one important reason for our inability to demonstrate a clear relation between chlorid excretion and edema lies in the great power of the body to retain fluid without the development of edema, for example, in one case of nephritis it was observed that feeding salt led to a marked retention of water, but edema did not begin to appear until the patient's weight showed that twelve pounds of water had been accumulated in the body. This power of retaining water without manifestation of edema makes it impossible to establish a close parallelism between the chlorid excretion and the edema, especially when the cases can not be studied very accurately for long periods of time.

Some observers have thought that the primary trouble in nephritic edema is the retention of water, to which the retention of salt is secondary, but the weight of evidence here seems to be that the chlorid retention is primary and the water retention is secondary. The retention of the chlorids seems to depend entirely on the inability of the kidneys to excrete them. Apparently the retained chlorids are held in the tissues throughout the body, for many analyses have shown a retention of chlorids in the tissues—the so-called histo-retention. The amount of chlorids in the blood is not, and can not be, greatly increased, for water must always accumulate to keep the osmotic concentration of the blood not far from normal. Why and how the chlorids accumulate in the tissues in excessive amounts is one of the unsolved problems.

There seems to be no tendency on the part of those who question the general importance of chlorid retention in the etiology of edema to deny the facts brought forward by Widal and others, which show that in at least some cases this retention is the cause of the accompanying edema. The chief question is: How often does edema depend on chlorid retention, and how often is this factor absent or of minor importance as compared with the other possible causes of edema that may be present in nephritic patients? The answer to this question can not possibly be given on the strength of the information afforded by the discordant reports that are to be found in the literature, but it seems safe to say that chlorid retention is an important factor in a very considerable proportion of nephritic edemas. Chlorid retention has also been observed in some cases of dropsy in heart disease, and with some edemas occurring in patients with acute inflammatory disorders, but here it is

¹ A full bibliography of this subject will be found in the résumé by Martin Kaufmann, *Centrbl. f. d. gesamte Physiol. u. Pathol. des Stoffwechsels*, 1906, vii, 497.

not so well established that the observed chlorid retention is more than can be explained as due to the retention of the fluid in the edematous parts

In any case however, the treatment of renal dropsy by "dechloridization therapy" seems to be warranted on several grounds. In the first place, of course, comes the indication that in many cases edema is relieved by this means, the amount of chlorids excreted on a chlorid-poor diet being much in excess of the amount taken in, such a diet soon leads to removal of the retained chlorids and with them the retained water. Secondly, there is considerable evidence that chlorids may act injuriously on the diseased kidneys, indeed, excessive quantities of sodium chlorid may cause albuminuria even in healthy individuals, which observation suggests the possibility that the use of oversalted foods may be an important factor in the production of nephritis. It seems to have been commonly found that nephritic patients kept on a chlorid-poor diet show a decreased amount of albumin in the urine, while administration of chlorids causes it to increase. Furthermore, there is abundant evidence that there is no danger in reducing the intake of chlorids to as low a figure as can be done by a carefully selected diet. To reduce the chlorids to such a reasonable minimum, say from 2 to 3 grams a day, no very difficult procedures are necessary, for in eggs, unseasoned meats and unsalted butter we have foods that are nearly salt-free while the salt content of milk is very low. Bread without salt, fresh water fish, potatoes, rice, fresh vegetables, fruits and chocolate offer a considerable variety of salt-poor foods that make the regulations of a dechloridization diet not intolerable to the patient. It may be added that Widal insists on repeated weighing of the patient, in order to keep track of the degree to which the water is being removed during the treatment.

THE MEDICAL STAFF AND THE HOSPITAL

The importance of hospitals to the community is now so universally acknowledged that it needs no comment, the organization of hospitals, on the other hand, and the proper relationship which should exist between the medical staff, the administrative officers and the public is a matter which has been treated in this country in far too haphazard a manner. Every hospital trustee, every superintendent and every member of a hospital staff should read the admirable discussion of hospital organization which has recently appeared from the pen of Dr. Goldwater¹ of Mount Sinai Hospital, New York City.

Goldwater's article discusses seriatim, in a clear and forcible manner the medical staff in relation to the needs of the patient, in relation to medical education in relation to hospital economy, and in relation to the rights of its members. It is not the place here to cover the entire ground passed over in this article. Let it suf-

fice to call attention to some of the salient points, particularly those which refer to details of administration differing from those currently in use in this country. The stress which is laid on the importance of having the admission of patients under the control of mature medical men of good judgment rather than under inexperienced junior house officers, strikes us as well worthy of attention. We would not like to say how much of the popular prejudice against many hospitals is due to tactless handling of applicants for admission particularly of rejected applicants. There is little doubt that an unfavorable first impression is often prejudicial to the hospital's interests and too often the entering patient is subjected to the attentions of attendants who seem to have the unhappy knack of acquiring the flip-pant callousness and disregard for other people's feelings which are often associated with ticket sellers and second-class hotel clerks. Regarding the care of the patient after admission, Dr. Goldwater emphasizes several points, none more worthy of emphasis than the necessity of visits at regular stated intervals by the attending staff. The quotation from Osler to the effect that the physicians should not only make their visits at stated hours, but should also stay stated hours is one which could be well heeded by many hospital visiting physicians.

The suggestions regarding the house staff show that from Dr. Goldwater's point of view, most American hospitals are woefully undermanned in this particular. We fully agree with the writer in this, as we do in his view that each interne should have both a medical and a surgical service to obtain proper breadth of view. The rule that no interne should be promoted to a higher grade who has not shown fitness in a lower one is on the books of far too few of our hospitals.

Two points of especial value are those relating to the family physician, and to the patient during the period of convalescence. Dr. Goldwater suggests that the family physician of a ward patient should have every encouragement to visit his patient in the hospital not to advise the regular staff but for the effect on the welfare of the patient. We thoroughly agree with this and hope that the narrow spirit which has heretofore prevented it in many hospitals will soon disappear. The suggestion that the patient's future be discussed during convalescence and that the hospital should keep in touch with various charitable institutions which may harbor and protect the patient from the necessity of too early work is of great value and is too often not considered in routine hospital work.

The discussion of the relation of the hospital to medical education is brief. The keynote of the remarks on this subject lies in the statement that the reason why teaching hospitals are at present so expensive is that only a few hospitals realize their responsibility in this direction. If all hospitals regarded teaching as a necessary and legitimate part of their functions the number of students assigned to each institution would be

¹ Am Jour Med Sci April 1907

small that practically no extra expense would be incurred. This is certainly the case so far as the large cities are concerned, for hundreds of charity beds in cities like New York and Chicago are never adequately used for teaching purposes. Dr. Goldwater's paper also contains many pertinent remarks concerning the private ward system, the necessity of presenting the economic side of hospital affairs to the medical staff, and the representation of the medical staff in the affairs of the hospital.

THE RELATIVE VALUE OF CULICIDES

Disinfection for the prevention of yellow fever and malaria having practically resolved itself into mosquito destruction, the scientific study of culicides has assumed much interest and importance. Investigations in this direction are being made by the United States Public Health and Marine-Hospital Service.

Passed Assistant-Surgeon Francis of that Service some time ago reported that the fumes of pyrofume, a liquid derived by fractional distillation from pine wood, are deadly to *Stegomyia fasciata* and *Culex pungens*.¹ Mosquitoes placed in cages on the floor of a room containing the fumes from 265 cubic centimeters of this liquid per 1,000 cubic feet of air space were found dead after one hour. While in this proportion pyrofume is not injurious to metals, fabrics, paint and colors, it has been found that in greater amounts it softens varnish and leaves a deposit on surfaces. Its inflammable nature will also render it objectionable as a culicide until a generator is devised that will evolve the gas without danger.

Francis has more recently reported a series of experiments on the culicidal properties of camphor-phenol and of sulphur.² The camphor-phenol was made as follows: The phenol crystals were liquefied by placing the bottles in boiling water, the liquid was then poured into a pan and weighed, and to the hot liquid was added an equal weight of gum camphor, which became dissolved after standing a few hours.

In these experiments great care was taken artificially to protect the mosquitoes in such a way as to simulate the conditions which ordinarily aid the mosquito in escaping the effects of harmful gases. As a result of forty-two experiments on 10,000 mosquitoes he concludes that the fumes of camphor-phenol possess no powers of penetration that they diffuse poorly, and that they are diminished in efficiency by low temperatures. Mosquitoes show a tendency to recover from the effects of this agent, and varnish is softened when the fumes are strong—an evident disadvantage in the treatment of furnished houses and cabins aboard ships.

Twenty-four experiments with sulphur confirmed the value of this agent so long used in quarantine practice. Small quantities of sulphur proved effective in tests de-

manding all the necessity for penetration and diffusion likely to be found in practical fumigation. Unfortunately, the fumes of sulphur are in a measure destructive, otherwise it would meet all the requirements of a gaseous culicide. The well-known poisonous effects of hydrocyanic acid fumes are sufficient to discourage their use in actual practice, and in view of these studies it appears that we must for the present at least continue to rely on sulphur as the most efficient insecticide.

MAJOR KEAN AND THE SANITARY TRIUMPH IN CUBA

One of the incidents connected with the relations of this country to Cuba, of which Americans can be justly proud, is the improved hygienic conditions that resulted when the United States assumed control after the Spanish-American war. The Army of Occupation found very insanitary conditions. The administration and management of almshouses, asylums, orphanages and hospitals of all sorts and sizes had fallen into a chaotic condition throughout the island. Some of the institutions had means but only a few inmates, others were almost without money to keep the unfortunate inmates from actual starvation and yet were crowded with patients. There was a lack of system everywhere.

General Wood cast about for men to bring order out of chaos, the conditions demanded men above the average, who understood the needs of such institutions, and with a faculty for organization. Major J. R. Kean, surgeon, U. S. Army, was one of those selected. His work in putting the organization of the institutions of Cuba, especially the hospitals, on a sound and scientific basis was of great value and was mentioned in flattering terms both by the Military Governor and the Secretary of War. The result was a brilliant success, a symmetrical and well-organized system. While this work of Dr. Kean was appreciated at the time by those who were in a position to know what was going on, it attracted very little public attention.

At that time the general hygienic conditions also were in a deplorable state, Havana was one of the most filthy and most unhealthy cities of the world. When it was turned over to the Republic of Cuba it had become one of the cleanest and healthiest, considering the latitude. Similar work went on under American officers all over the island. One of the men to whom special credit was due for the improved conditions was Major Kean, who, as chief surgeon under General Fitzhugh Lee, had charge of some of the most important functions connected with the cleaning up of Cuba.

When the American Army of Pacification was sent to Cuba last October it was found that conditions had deteriorated under the independent Cuban régime, yellow fever was prevailing in the island, a dozen cases being in Havana alone. Thus our troops were endangered by a disease which while not regarded seriously by the Cubans, might result most disastrously to the

¹ Public Health Reports, xxi, No. 26.
² Public Health Reports, xxii, No. 14.

soldiers The provisional government being essentially military in character, it fell to the Medical Department of the Army to supply an officer to take charge of the sanitary affairs The Secretary of War selected Major Kean, and to him and to his assistants must be given credit for the splendid results which followed Our news columns have shown week by week a gradual decrease in the number of yellow fever cases reported, Havana having not a single case since January 1, and the island itself being free from the disease Since January 10 there has not been a case of yellow fever, among the enlisted men, and only one officer contracted the disease This task also required intelligent, faithful and persistent effort, and Major Kean and his assistants furnished it Working under the difficulties of a strange language and an ignorant population intensely conservative in its habits of life, they have accomplished a task that is a credit to the country and to preventive medicine

It is a pity that such work should go unrecognized by the general public, for it is certainly as praiseworthy as any incident connected with our relations with Cuba Probably if what might have resulted were a known rather than an unknown quantity, if it were known that certain thousands of soldiers would have been disabled by sickness, and that a definite number would have died had these essentials of preventive medicine not been carried out, the public would show its appreciation and would acknowledge its debt for such work to the men who did it and to preventive medicine in general

THE BUSINESS SIDE OF MEDICINE IN CANADA

The failure on the part of the medical profession to take due thought of the practical and material side of its work has often been noted A Canadian writer¹ recently made the statement, based on the experience of a medical friend, that through indifference and want of cooperation many physicians in the larger cities are living "very near the edge of want and ordinary comfort" That this is relatively true in the United States will be doubted by no one who is well acquainted with the personnel of the profession in the large centers of population, and apparently the same conditions obtain among our northern neighbors The conclusion follows that we are negligent in our duty to our families, not only so far as present necessities are concerned, but also for the future This is all the more apparent when we consider the universal tendency toward organization and the confederation of common interests now going on in all lines of industrial and professional life These conditions in the medical profession are largely the result of indifference and as the writer says we have, through indifference, "the establishment of osteopathy, chiropractic, etc Through indifference we hang on the walls of our offices dazzling chromos of 'patent-medicine' companies Through indifference we take journals—called medical—whose almanac character is easily noticed Through indifference Eddicism and other delu-

sions interfering with medical practice are allowed Too much study do we give to phagocytosis and opsonins, tubercle bacilli and the *Stegomyia fasciata* and too little to *materia medica*" And it might be added, too little study do we give to those problems of medical economics on which the future success of the profession depends It is evident that the same practical problems are confronting our professional brethren in Canada that we have before us here It is also evident that many physicians are beginning to ask the reason for existing conditions and are making efforts to determine the best means of remedying them Such signs of the times are encouraging and lead to the hope that the renaissance in medicine which so far has been confined to its scientific achievements, may also extend to the economic conditions that are at present presenting such perplexing problems

STEGOMYIA CALOPUS THE YELLOW FEVER MOSQUITO

We are informed that "*Stegomyia calopus*" has been adopted by the Public Health and Marine-Hospital Service and by the Bureau of Entomology, Department of Agriculture, as the official name of the yellow fever mosquito In the matter of nomenclature this insect has undergone many vicissitudes Among the names by which it has been known, *Culex fasciatus*, *Culex calopus* and *Stegomyia fasciata* are the most familiar The mosquito since recognized as responsible for the spread of yellow fever was originally classified as a *Culex* and received over a century ago the title *Culex fasciatus*, a name previously bestowed on an insect not identical with the one in question The term *Culex calopus* was proposed somewhat later and with the recent transference of this mosquito to the genus *Stegomyia* the name *Stegomyia calopus* resulted

Medical News

DISTRICT OF COLUMBIA

Graduation Exercises.—The graduation exercises of the United States Naval Medical School were held in Washington, March 30, when diplomas were given to a class of 28 by Assistant Secretary of the Navy Newberry The principal address was made by Dr J Chalmers Dr Costa Philadelphia, and addresses were also made by Surgeon General Presley M Rixey and Medical Director John C Wise, U S Navy, president of the faculty of the school

Illness of Major Carroll.—Major James Carroll of the Medical Department of the Army who was promoted from the grade of first lieutenant to that of major by special act of Congress in the last hours of the recent session as a reward for his distinguished services as a member of the yellow fever commission in Cuba has been quite ill at his residence in Washington for the last two months Major Carroll is suffering from a continued fever of an obscure character, and while he has not at any time been in a dangerous condition his continued illness has caused more or less uneasiness to his friends At the present time he is improving and it is hoped that he will soon be able to resume his duties

ILLINOIS

Personal.—Dr Max F Clausius, Palatine, has removed to Norwood Park —Dr Nel on K McCormick Normal has been appointed medical director of Broward —Dr Fred Pose Columbia was a accidental discharge of a shotgun while was taken to Henrietta Hospital East

¹ Sprague (U S) Medical Thoughts Facts Fads and Fancies Canada Lancet 1 February 1907

Railway Surgeons Meet—What will be known as the T, P & W Railway Surgeons' Association was organized at Peoria, April 1. The organization expects to be affiliated with the American Association of Railway Surgeons. The visiting surgeons were the guests of Dr. Elmer M. Eckard, surgeon in chief of the Toledo, Peoria & Western Railroad.

Chicago

Gift to Charity—The Chicago Women's Aid Society at its recent meeting donated \$1,000 to the Michael Reese Hospital for use in the children's ward.

Interne Examination—As a result of the examination of the 98 students at the Cook County Hospital recently, 44 students passed the required grade. Fifteen of the successful applicants will be appointed internes in June.

Deaths of the Week—For the week ended April 6, 686 deaths were reported, or 58 less than for the preceding week, and 26 less than for the corresponding week of last year. This is equivalent to an annual death rate per 1,000 of 16.97.

Increase in Deaths—The greatest increase in death causes for the first quarter of 1907, as compared with the corresponding period of last year, was from pneumonia, with a total of 1,860 deaths, or 552 more than in 1906, scarlet fever, with 220 more, tuberculosis, with 120 more, and heart diseases with 156 more.

Mortality of the Quarter—During the three months ended March 31, 9,104 deaths were reported, equivalent to an annual death rate of 17.52 per 1,000, an increase of 22.2 per cent over the death rate for 1906 for the same period, which was 14.34 per 1,000. Among the principal death causes were pneumonia, 1,860, consumption, 1,014, heart disease, 690, Bright's disease, 582, and violence, including suicide, 545.

Pure Food Show—It is announced that the first World's Pure Food Show will be opened in the Chicago Coliseum November 19 and will continue for one week. The test committee for the exhibit will consist of Dr. Harvey W. Wiley, Washington, D. C., Drs. John H. Long, Ralph W. Webster, Archibald L. Hovne and Joseph F. Biehn, of Chicago, Prof. Julius Stieglitz of the University of Chicago, and Dr. James A. Egan, secretary of the State Board of Health.

March Mortality—During March 3,065 deaths were reported, or 602 more than for the corresponding period of last year. Pneumonia caused 657 deaths, consumption, 300, heart disease, 241, Bright's disease, 188, violence, including suicide, 177. Deaths from scarlet fever diminished, as compared with last month, from 142 to 87, those from diphtheria from 51 to 32, those from typhoid fever from 33 to 21, those from influenza from 36 to 28, and those from measles from 32 to 18.

MARYLAND

Hospital Report—The report of the Washington County Hospital, Hagerstown, for its first year, showed that the receipts were \$10,245, and the disbursements \$12,542. There were 106 patients admitted, of whom 75 were surgical and 31 medical cases. There were 72 operations performed, and 17 deaths occurred during the year, equivalent to an annual death rate of 16.03 per 1,000.

Baltimore

Mosquito Question—The city council ordinance for the prevention of breeding of mosquitoes will become operative May 1. The carrying out of the ordinance is in the hands of the health department and \$10,000 has been placed at its disposal.

Tuberculosis—The University of Maryland Nurses' Alumni Association gave an entertainment April 5 for the support of tuberculosis nursing among the poor. A committee has been appointed to study the tuberculosis situation in the state and to supervise the expenditure of the \$10,000 recently raised for this purpose.

Illegal Practitioners—On the testimony of the State Board of Medical Examiners the grand jury is said to have found presentments on the charge of practicing medicine without a license against James E. Creevy, R. Crowley, Robert H. Darrah, D. Romeo and Pasquale Romeo. It is said that the law is constantly being violated by medical students and druggists.

Personal—Dr. J. M. T. Finney spoke at the last of the men's meetings held at Belair Harford County March 31.—Dr. Stephen H. Watts of Johns Hopkins University has been elected professor of general surgery in the University of Virginia and director of the University Hospital.—Dr. L. Ernest Neale was operated on for appendicitis at St. Joseph's Hospital April 5.—Dr. Lewis M. Allen was elected vice

president, and Dr. Gordon Wilson, a member of the executive committee, at a recent meeting of the Society of Virginia University Alumni in Maryland.—Dr. William H. Welch lectured on tuberculosis and its problems at the Johns Hopkins Medical School, April 4.—Dr. Frank Bressler sailed for Jamaica, April 3.—Dr. Harry W. Plaggemeyer has been appointed interne at King's County Hospital, Brooklyn, N. Y.

MISSISSIPPI

Communicable Diseases—The secretary of the State Board of Health reports the state to be in an exceptionally healthy condition. The smallpox contagion has abated in many communities, where it was reported during the winter. The disease is still present in mild type in a few localities in the delta.

Hospital Staff—The following physicians have volunteered to give their services to the King's Daughters Hospital, Gulf port. Emergency surgeons, Drs. Hunt and Robert W. Shipp, female medical ward, Drs. Henry S. Capps, A. L. Morris and Barnes, male medical ward, Drs. Crawley, Heard, H. West and W. T. Hutchins, female surgical ward, Drs. Charles LeBaron, Charles A. Sheeley and Mathis, and male surgical ward, Drs. Robert A. Anderson and Edward C. Parker.

Commencement—The first annual commencement exercises of the Mississippi Medical College, Meridian, were held March 30, when a class of 22 received diplomas. Dr. William W. Hamilton, president of the faculty, presided, Dean Nathan L. Clark gave a short historical review of the institution, Mr. Edwin McMorris, president of the board of trustees, awarded the diplomas, and Dr. W. T. Lowry, president of the Clinton (Miss.) College, delivered the annual address.

Society Meeting—At the annual meeting of the Attala County Medical Society, held in Kosciusko, March 18, the following officers were elected: President, Dr. Edward C. Coleman, Kosciusko, vice president, Dr. Charles F. Carnes, Kosciusko, secretary treasurer, Dr. John H. Portwood, Kosciusko, and censor, Dr. Thomas F. Turner, Smyrna. The question of fees for life insurance examination was discussed, but final action was deferred until after the meeting of the state association.

MISSOURI

Emergency Hospital—An emergency hospital in the basement of the city hall of Kansas City was opened to receive patients March 30. The hospital equipment consists of two wards, one with eight cots for men, and one with four cots for women, and an emergency operating room.

Pasteur Institute in St. Louis—A Pasteur institute, for the free treatment of hydrophobia, has been established at the city bacteriologist's office in the City Hospital. Dr. Downey L. Harris is in charge of the institute, for the use of which five rooms have been assigned.

Medical Branch of University Offered to Kansas City—The curators of the Missouri State University met the mayor of Kansas City and a special council committee to discuss the establishment in Kansas City of a medical branch of the university, and proposed that the medical administration of the municipal hospitals of the city should be given to the medical department of the university, which would take off the hands of the city the burden of maintenance of hospitals, so far as drugs, surgical supplies, doctors, nurses and attendants are concerned.

Personal—Dr. David T. Bailey, Trenton, has been appointed physician of Grundy County.—Dr. Francis R. Anthony, Maryville, has succeeded Dr. Kieran C. Cummins, Maryville, as physician of Nodaway County.—Dr. Claude C. Crowley, Richmond, county physician, has been elected secretary of the Ray County board of health.—Dr. Julius H. Weinsburg, St. Louis, was shot and seriously wounded by his son, March 18.—Dr. Hugo M. von Starkloff, St. Louis, sustained severe contusions of the hip in a collision between his buggy and a trolley car, March 20.

Society Organized—Dr. William T. Elam, St. Joseph, counselor for the seventh district, met the physicians of Andrew County at Savannah March 20 and assisted in the reorganization of the county medical society, with 15 charter members. The following officers were elected: President, Dr. Elijah C. Bennett, Bolckow, vice presidents, Drs. John C. Hoshier, Rosendale, Sumner S. Beever, Amazonia, Ernest H. Carpenter, Helena and Walter C. Myers, Rea, secretary treasurer, Dr. Clarence O. Jefferies, Savannah and delegate to the state association Dr. Elijah C. Bennett, Bolckow. Dr. Charles Wood Fassett, St. Joseph, read a paper on 'The Benefits of Medical Organization.'

NEW YORK.

Gift to Sanitarium.—John D. Rockefeller and Anson R. Flower have each given \$12,500 to the Lake Kashaqua Sanitarium for Sick Working Girls, in the Adirondacks, and this gift will rid the institution of debt.

For Syracuse Hospital.—It is announced that Mrs. Russell Sage has given \$5,000 toward the permanent endowment fund of the Hospital of the Good Shepherd, Syracuse, to be used for the maintenance of a free bed in the hospital.

Medical Club Election.—At the annual meeting of the Utica Medical Club, March 14, the following officers were elected: President, Dr. Andrew Sloan, vice president, Dr. William S. Nelson, secretary treasurer, Dr. William H. Beattie, and trustees, Drs. Morris J. Davies, William J. Schuyler and Edwin Van D. Gazzam.

Reception to Mueller.—On March 30 the Albany County Medical Society gave a reception in the rooms of the Albany Historical and Art Society in honor of Dr. Frederick Mueller, professor of medicine in the University of Munich. During Dr. Mueller's stay in Albany he was the guest of Drs. Henry L. K. Shaw and Andrew MacFarlane.

Personal.—Dr. Roswell Park, Buffalo, is taking a trip to Cuba. Dr. William R. Campbell, Niagara Falls, was operated on by Dr. Carlton C. Frederick, Buffalo, for cancer of the liver, March 21. Dr. H. John Hunter has been elected health officer of Ithaca. Dr. Joseph E. Vigeant, Red Hook, was seriously injured at Elizaville, March 14, while attempting to board a train in motion.

Site for State Hospital.—A bill has been introduced into the legislature authorizing the state lunacy commission to select lands for a site for a state hospital for the insane in the southeastern part of the state. The lands selected not to comprise more than 1,000 acres. This commission is to report to the legislature of 1908 in respect to the lands selected, giving reasons why they are desirable.

Quarantine Hospital.—In a report made to the health commissioner of Buffalo by Dr. Francis E. Fronczak, assistant health commissioner, he states that he finds the hospital in very good condition and ready to care for any smallpox patient who might be sent there, but says he can not see why this expensive hospital should be continued at such a cost to the city without a single smallpox patient when there is such a great and immediate need of a hospital to care for individuals suffering from other infectious diseases. During the year ended March 31 there were reported to the board of health 2,003 cases of measles, 618 cases of scarlet fever, 530 cases of diphtheria and 287 cases of varicella and many other communicable diseases, but only one case of smallpox, and that of a very mild type.

Bills in the Legislature.—An act regulating cigar making has been introduced by Mr. Gluck, which provides that it shall be unlawful for any person making cigars to place any cigar or the materials composing it in the mouth, or to touch them with the lips during and as part of the making. An act to amend the public health law in relation to the adulteration or misbranding of food or drugs provides that the term "food" shall include every article of food and every beverage used by man, that the term "drug" when so used shall include all medicines for internal or external use. A bill amending the code of criminal procedure and designed to do away with the now famous hypothetical question in cases where the sanity of the defendant is at issue has recently been introduced in the state assembly. On April 4 the assembly amended the so-called medical unification bill which provides for one board of medical examiners. Under the original bill it was contended that surgery might be practiced by osteopaths.

Pollution of Ice.—Dr. Porter, state health commissioner, in a paper on the "Pollution and Self Purification of Ice" published in the monthly bulletin of the health department, states that a bill will be introduced into the legislature giving the department supervision over the business of harvesting and distributing natural ice. He shows the ways in which ice may be contaminated and also that about 50 per cent of the bacteria in the ice would perish from exposure to the cold, and that many bacteria would be so lowered in vitality as to be incapable of producing disease. He said the real dangers are those incident to handling and distribution, to surface pollution due to flooding the ice in order to get a thicker crop, etc. The Empire State Ice Association which has just held a convention protested against the impression that the ice taken from the Hudson was impure and unfit for domestic use. It

was stated that New York City, which used the greater part of the supply, had the lowest death rate from morbid germ diseases of any city of considerable size in the country. The report of Dr. Jackson was criticised because the samples analyzed were from cakes of ice from which the surface had not been planed.

New York City.

Personal.—Dr. Gordon Lindsay, senior surgeon at Bellevue Hospital, has been removed to Minton Hospital, critically ill with diphtheria. Dr. and Mrs. Thomas L. Stedman sailed for Europe on the Holland American steamship *Voordam*, April 3.

Internes Ill.—Dr. Horace W. Frank of Bellevue Hospital is seriously ill with blood poisoning due to an infection received during an operation. Dr. Marcel W. Sherwood, interne at Bellevue Hospital, was removed to the Minton Hospital, March 28, seriously ill with diphtheria.

Pneumonia and Tuberculosis.—According to the winter report of the Health Department, pneumonia has succeeded tuberculosis as the chief death cause. During the three months from Dec. 8, 1906, to March 9, 1907, the deaths from pneumonia in Greater New York were 4,519, while those from tuberculosis numbered only 2,490.

Bequests.—Daniel Vincent, who died in St. Vincent's Hospital, March 20, bequeathed \$35,000 to the Society of St. Vincent de Paul. By the will of the late William C. Eggleston, St. Luke's Hospital will receive \$100,000. The will also gives \$20,000 to St. Mary's Free Hospital for Children, and \$15,000 to the New York Institution for the Blind.

Jubilee of Dispensary.—The fiftieth anniversary of the German Dispensary was celebrated by a dinner at Hotel Astor, March 16. This function concluded the dedicatory exercises of the new Ottendorfer Dispensary. More than 300 physicians and surgeons on the staff of the German Dispensary and German hospitals of New York were present. Dr. Pius Renn was toastmaster and souvenir medals were distributed to the guests.

Contagious Diseases.—There were reported to the sanitary bureau for the week ended March 30, 434 cases of tuberculosis with 221 deaths, 419 cases of measles with 5 deaths, 379 cases of scarlet fever, with 17 deaths, 311 cases of diphtheria, with 41 deaths, 120 cases of typhoid fever, with 15 deaths, 54 cases of whooping cough, with 9 deaths, 26 cases of cerebrospinal meningitis with 20 deaths and 70 cases of varicella, a total of 1,815 cases and 328 deaths.

Typhoid on the Croton Watershed.—There have been six cases of typhoid fever in the Italian camp at the Cross River dam, which is under process of construction, ten at Katonah and one at Bedford where sewage flows into the city's water supply. A comparison of the number of cases of typhoid fever in this city for the week with the corresponding week of last year shows a notable increase in the number of cases, and every effort is being made to protect the water supply. An experimental filtration plant has just been put into operation at Jerome Park reservoir and the results will be noted daily.

Mayor Appoints Milk Commission.—The recent discussion over the problem of securing a pure milk supply for the city has resulted in the appointment of a milk commission by the mayor. The following men will serve on the commission: Drs. D. J. Bryant, former president of the board of health, T. Mitchell Prudden, Rowland C. Freeman, L. Emmett Holt and Abraham Jacoby. The work of this commission will be entirely independent of the board of health or any other city department. Any ordinance passed by the board of aldermen will have to receive the sanction of this commission before the mayor will give his signature.

NORTH CAROLINA.

Personal.—Dr. W. H. Smith, Goldsboro, has removed to Philadelphia. Dr. James McKee has been re-elected superintendent of the Central State Hospital for the Insane, Raleigh, and Drs. Edwin P. Ferrellee and Charles J. Jenkins, assistant physicians for a term of four years.

Date of State Society Meeting Changed.—The committee of arrangements of the Medical Society of the State of North Carolina at a recent meeting changed the date of meeting from May 28 to 30 to June 11 to 13 at Morehead City. This will allow the members to attend the meeting of the Surgeons of the Southern Railway at Washington, May 28 to 30, the Tri-State Medical Association at Norfolk, June 2 to 4, and the American Medical Association at Atlantic City, June 4 to 7.

State Hospital Commission Organized—The State Hospital Commission, recently created by the legislature, met in Raleigh and organized by electing Charles A. Webb, president, and Dr J W McNeil, Fayetteville, secretary. The commission has arranged for the purchase of 1,200 acres of land adjacent to the Central Hospital, Raleigh, with the idea of making extensive additions to the institution on the colony plan. Large additions of land will be made to the institutions at Goldsboro and Morgantown. The legislature has placed \$500,000 at the disposal of the commission for the improvement and extension of the state's facilities for the care of the insane.

OHIO

New Journal—A new monthly medical journal, called the *Diagnostician*, has made its appearance in Cincinnati.

Hospital Notes—The report of St Anthony's Hospital, Columbus, for 1906 shows that 1,085 patients were treated during the year, with 64 deaths, one half of which were due to tuberculosis of the lungs. The new hospital at Warren is nearing completion and will probably be dedicated in June. The building has cost about \$40,000. Miss M E Surbray, Akron, has been appointed superintendent of the hospital.

Epidemic Diseases—Chagrin Falls reports at least 200 children ill with measles, and that the public schools have been closed on this account. Dr Charles O Probst, Columbus, secretary of the State Board of Health, visited Castalia March 25, to investigate the epidemic of cerebrospinal meningitis. Thirteen deaths have occurred in and near Castalia and one new case was reported April 1, making 18 cases in all. One death from cerebrospinal meningitis is reported in an adult in Toledo.

Personal—Dr Albert E Griffin, Columbus, who was recently operated on for appendicitis, has been discharged from the hospital. Dr John L Davis, for many years medical director of the Union Central Life Insurance Company, Cincinnati, has resigned to accept a similar position with the Pacific Mutual Life Insurance Company, San Francisco. Dr George W McCoy, interne at the City Hospital, Cincinnati, has been appointed resident physician at the Manhattan Eye and Ear Hospital, New York City. Dr Augustus C Schwartz, city health officer of Tiffin, has been elected physician of the Seneca County jail for one year, vice Dr A M Campbell, term expired. Dr James F Heady, Glendale, has been elected professor of medical economics in the Miami Medical College, Columbus. Dr Katharine R. Moses, in charge of the female department of the Cleveland State Hospital, has resigned. Dr Edwin Reinert, Columbus, has been appointed a member of the board of public safety. Dr Harry E Welch has been re-elected health officer of Youngstown. Dr Arthur E Osmond, resident physician at the City Hospital, Cincinnati, has resigned.

Society Secretaries to Meet—The Ohio State Medical Association has arranged for a convention of the county society secretaries of the state to be held at Columbus, April 25, for a discussion of the work of county secretaries and for devising methods to facilitate and increase the effectiveness of the secretaries' work. A program, lasting throughout the day, is to be opened by an address of welcome by Dr Frank Winders, secretary of the Ohio State Medical Association. The following papers will be presented: "The Relation of the Secretary to the Society and the Profession" Clyde E Ford, secretary of the Cleveland Academy of Medicine and the Cuyahoga County Medical Society; "The Relation of the Secretary to the Council" T W Rankin, Columbus, counselor of the Eighteenth District; "The Relation Between Local and District Societies" J S Rardin, Portsmouth; "How the Secretary's Work May be Made Easier," Carrie Chase Davis, Sandusky, secretary Erie County Medical Society; "My Plan for the Struggle" Nellie B Kennedy, Findlay, secretary Hancock County Medical Society; "What Can a Secretary Do to Secure New Members" John B Donaldson, Lorain, secretary Lorain County Medical Society. During the noon intermission lunch will be served at the Neil House. The afternoon session will be opened by an address on "Medical Legislation" by Charles A J Reed, Cincinnati, chairman of the Committee on Medical Legislation of the American Medical Association. John B Donaldson, Canonsburg, Pa, secretary of the Washington County (Pa) Medical Society will read a paper on "The Secretary and His Opportunity" after which papers will be read by Herschel Fisher, Lebanon, secretary of the Warren County Medical Society on "How Can We Make 'Open Meetings' Most Successful?" by Horace Bonner, Dayton, counselor of the Second District on "The Social Factor in the Life of the Successful Physician,"

and by O M Wiseman, Zanesville, on "Our New Doctors." Papers by R H Grube, Xenia, secretary Greene County Medical Society and N Worth Brown, Toledo, secretary Toledo and Lucas Academy of Medicine, on the value of graduate courses to medical societies in the country and in the city, will close the program. A large attendance of the county secretaries of the state is anticipated and it is hoped that much benefit to the organization will result from the meeting.

PENNSYLVANIA.

Golden Jubilee of Physicians—Dr Jonathan L Forwood, mayor of Chester for four terms, and chief of the surgical staff of Chester Hospital, one of the best known physicians and surgeons in the city, celebrated the fiftieth anniversary of his entry into the profession April 7. The Delaware County Medical Society had arranged to give a banquet in honor of this event, but by the special request of Dr Forwood gave up the idea.

Ambulances in Coal Mines—It is reported that car ambulances are to be introduced in the anthracite coal mines of the state to facilitate the work of the first aid to the injured corps. The ambulance cars resemble the ordinary mule cars but have springs, and two upholstered stretchers so arranged that either may be used exclusively. Each car has a full emergency equipment. The mine workers in the first aid corps are enthusiastic over the ambulance car idea.

Hospital for Criminal Insane—At a meeting held April 5, at Honesdale, plans for the new State Hospital for the Criminal Insane were discussed. Options on several hundred acres adjoining the site of 600 acres presented to the state by the Delaware & Hudson Railroad were obtained, and this land will be paid for from the appropriation of \$10,000 for a site made by the last legislature. Assurance has been given the commission of an appropriation of \$150,000 to start building, by the present legislature. The site for the administration building, which is the first to be erected, was selected. This building will contain the offices and quarters for the executive officers and accommodations for probably 100 patients. It is the intention of the commission to build an institution capable of caring for 1,000 patients, the cost of which will be eventually more than \$1,000,000.

Communicable Diseases—Of the 87,757 cases of communicable diseases reported to the State Department of Health during 1906 there were 24,421 cases of typhoid fever, 6,002 cases of scarlet fever, 10,842 cases of diphtheria and 23,729 cases of measles. The following diseases are classed as communicable: Actinomycosis, anthrax, bubonic plague, cerebrospinal meningitis, chicken pox, cholera, diphtheria, epidemic dysentery, erysipelas, German measles, glanders, hydrophobia, leprosy, malarial fever, measles, mumps, pneumonia (true), puerperal fever, relapsing fever, scarlet fever, smallpox, tetanus, trachoma, trichinosis, tuberculosis, typhoid fever, typhus fever, whooping cough and yellow fever. The statistics of communicable diseases are to be analyzed by the department of health for the purpose of comparing them with the record of deaths from the same diseases. These statistics should be valuable in the immediate fight against disease throughout the state and in addition will furnish permanent data for the study of social conditions and will be helpful to the students of remedial legislation.

State Board Examination—The next examinations of the Pennsylvania State Board of Examiners will be held at Harrisburg June 25 to 28 in Russ Hall 15 North Second Street and City Grays' Armory corner Second and Forster streets. The first session will begin at 9 a m June 25. All candidates must have their credentials completed and have cards from the secretary of the medical council to present at the door at the time of examination. Every candidate will be required to furnish a cabinet photograph of himself, endorsed in his own handwriting on the back and endorsed on the back by the dean of the college from which he graduated certifying to the correctness of the photograph and to the genuineness of the signature. In cases where the dean has died or the college has ceased to exist an affidavit signed by the candidate must accompany the signed cabinet photograph. Candidates desiring to file applications should apply to Dr N C Schaeffer, secretary of the medical council Harrisburg or in the matters relating to work of the board to Dr W D Hamaker, secretary of the Board of Medical Examiners, Meadville.

Philadelphia

Bequests—According to the will of Frederick Bauer, \$1,000 is left to the German Hospital. The late Nicholas J. Lennig

devised \$10,000 to the Maternity Hospital and \$1,000 to the Philadelphia Dispensary

Deaths of the Week.—The number of deaths from all causes in the week ended April 6 was 617, a decrease of 38 from the number reported last week. The chief causes of death were Typhoid fever, 13, diphtheria, 10, cerebrospinal meningitis, 12, tuberculosis, 75, cancer, 28, pneumonia, 77, and Bright's disease 50

Personal.—Dr Joseph Neff has been appointed director of public health and charities, to succeed Dr W M Late Coplin. Dr Neff is a member of the faculty of Jefferson Medical College and is medical director of the Jefferson Hospital.—Dr A Lee Clifton, who has been resident physician at the Delaware Hospital since June, has been appointed a resident physician of the University of Pennsylvania, under Dr John Clark.

Hospital Notes.—The report of the Wills Eye Hospital shows that during 1906, 800 new patients were admitted for operation and treatment and the clinics gave free service to 10,000 new and 80,000 old patients, from 63 counties of Pennsylvania, an average of about 300 a day. The hospital is badly in need of extensions and additions to the building, and has asked the legislature to furnish them at an estimated cost of \$150,000 and allowance for maintenance of \$50,000 a year.

Endorses Bill Controlling Marriage.—The Philadelphia County Medical Society, at its meeting March 15, passed the following resolution:

Resolved That the Philadelphia County Medical Society notes with great satisfaction the introduction of a bill before the Legislature of Pennsylvania requiring certificates to the effect that both parties to a proposed marriage are in the opinion of a qualified physician free from disease transmissible to progeny. The society affirms the principle involved and endorses the effort of the community to secure the adoption of the measure.

Banquets.—At the annual banquet of the Davis Obstetrical Society, held March 23, Dr Edward P Davis, honorary president of the society, acted as master of ceremonies. Drs Hobart A Hare, J Chalmers Da Costa and H Augustus Wilson and members of the faculty of Jefferson Medical College attended the banquet.—The twenty-fifth annual reunion and banquet of the medical class of 1882, of the University of Pennsylvania, was held March 16, Dr Horace Javne presiding. Dr James Tyson, one of the three surviving members of the faculty at that time, was the guest of honor. Historical sketches were read by Drs Judson Daland and William J Taylor.

Alvarenga Prize.—The College of Physicians of Philadelphia announces that the next award of the Alvarenga prize, being the income for one year (\$180) of the bequest of the late Señor Alvarenga, will be made July 4, provided that an essay deemed worthy of the prize shall have been offered. Essays may be on any subject in medicine, but can not have been published. They must be typewritten and must be received by Dr Thomas R. Neilson, secretary of the college on or before May 1. Each essay must be sent without signature, but marked with a motto and accompanied by a sealed envelope, having on its outside the motto of the paper and within the name and address of the author.

Jubilee of Pathological Society.—Elaborate preparations are being made by the Pathological Society of Philadelphia to celebrate in a fitting manner the fiftieth anniversary of its founding. The morning of the first day, May 10, will be devoted to the welcoming of guests and to addresses by distinguished men from different parts of the country. A luncheon to members and guests will be served at the University Club at 2 p. m., and two hours later a commemorative meeting will take place in the amphitheater of the Pennsylvania Hospital where the first meetings of the society were held. Dr William Osler, regius professor of medicine Oxford University, will deliver the principal address. An exhibition of pathological specimens will be opened to guests, members and profession at large on Friday and Saturday in the Mütter Museum of the College of Physicians.

TENNESSEE

Officers Re-elected.—At the annual meeting of the State Board of Health April 7, Dr Helver Jones Memphis was re-elected president, and Dr Thomas E. Abernethy Chattanooga vice president.

Communicable Diseases.—More than 200 of the pupils of the schools of Knoxville are reported to be suffering with measles.—The smallpox situation in Weakley County is reported to be unimproved, several new cases having developed near Greenfield.

TEXAS

Health of the State.—State Health Officer William Brumby Austin, asserts that smallpox is spreading in certain counties of the state and that approximately 20 counties are affected.—An epidemic of measles is reported at Killean.

Personal.—Dr Roland C Connor, Roby, has been appointed on the medical staff of the Canal Zone.—Dr Aleck Spencer Temple, has resigned as health officer of Bell County and has been succeeded by Dr Taylor Hudson of Belton.—Dr O T Brundy, Milford has been appointed surgeon to the Confederate Home, Austin.

Hospital Notes.—The senate committee on public health made a favorable report, March 25 on the house bill appropriating \$150,000 for the establishment of a state sanitarium for tuberculosis.—The annual report of Sealb Hospital, Galveston, shows that in 1906 there were 40,556 hospital days, a gain of 4,434 as compared with 1905. The daily average of patients for the year was 111, and 1,550 patients were admitted.

War on Mosquitoes.—At the last meeting of the board of city commissioners of Galveston, Dr Charles W Trueheart city health officer, was granted permission to advertise for 120 barrels of crude carbolic acid for the use of the department during the coming summer to combat the mosquitoes and diminish the plague of house flies in the city.—The campaign against mosquitoes has commenced in San Antonio and good work is being done by the children of the public schools.

VIRGINIA.

Personal.—Passed Assistant Surgeon Rupert Blue of the United States Public Health and Marine Hospital Service has been made chief of the department of sanitation at the Jamestown Exposition.—Dr M F Hainsbrough, Front Royal was painfully injured in a runaway accident at his home March 30.

Honor to Dr Reed.—The State Library Board has appointed an art committee, of which Admiral Harrie Webster is chairman to select a portrait of the famous surgeon and bacteriologist, the late Dr Walter Reed major and surgeon United States Army who was born at Harrisburg Va to be placed in the library.

Anti Mosquito Crusade.—An anti mosquito crusade is to be inaugurated in Norfolk during the summer by Health Commissioner Dupuy of that city who will be assisted in the work by Surgeon Charles P Wertenbaker and Passed Assistant Surgeon Rupert Blue of the United States Public Health and Marine Hospital Service.

GENERAL

Yellow Fever in Cuba.—Major Jefferson R Kern U S Army reported on April 6 a case of yellow fever at Nueva Paz, in the southeast corner of Havana province. The patient was a Spaniard who had arrived from Spain December 14 and had not left the part of Cuba in which he was taken ill since that time. There is believed to be no reason to fear infection in Havana.

Internes Wanted in Insane Hospital.—The United States Civil Service Commission will hold examinations June 13 and 14, at the usual cities throughout the United States, to supply medical internes in the Government Hospital for the Insane, Washington D C. This examination is open to men who are citizens of the United States, aged 20 years or over and graduates of reputable medical colleges. Applicants should apply at once to the commission at Washington for application form 1312.

Attitude of the Filipinos Toward the Leper Hospital.—Dr Heiser, chief quarantine officer reports that a remarkable change seems to have come over the people in reference to their attitude toward the leper hospital. It is almost a daily occurrence for persons to apply voluntarily to the bureau of health for hospitalization. Many individuals have come from the colonies and requested that they be admitted to San Lazaro Hospital until they could be sent to the Cuban leper colony. These facts Dr Heiser states, are significant and point to an improvement in the attitude of the people.

Tropical Medicine Men Meet.—At the third annual meeting of the American Society of Tropical Medicine, held at the New York Academy of Medicine, Surgeon Leckowski W Spratt, U S Army, presented a paper on "Fever Sanitation" and Major L.

V, on "Observations on Health and Disease in Eastern Africa" The following officers were elected President, Dr James M Anders, Philadelphia, vice presidents, Drs Rudolph Matas, New Orleans, and William S Thayer, Baltimore, secretary, Dr John M Swan, Philadelphia, treasurer, Dr James Ewing, New York City, and members of the council, Drs Ramon Guteras, New York City, and Joseph McFarland, Philadelphia

New Roentgen Ray Journal.—The latest addition to medical periodicals is the *American Quarterly of Roentgenology*, of Pittsburgh, Pa, published by the American Roentgen Ray Society and edited by its president, Dr Preston M Hickey, Detroit, Mich This journal takes the place of the annual transactions of the society, and is the property of the society The first issue reflects great credit on the society and promises much for the future The policy of the society in reference to advertisements is not referred to in the editorial foreword, but judging from the advertisements that appear in the first issue, the pages are open only to those who have something to exploit that is of particular interest to roentgenologists The size of the journal is convenient and the mechanical work is excellent

Graveyard Regulations in the Philippines.—One of the most important sanitary measures—certainly one of the most difficult and laborious—according to Dr Heiser, of the bureau of health of the Philippine Islands is the regulation of the cemetery question in accordance with the law, which states that it shall be unlawful to establish, maintain, enlarge or remove any burial ground or cemetery until a permit therefor shall have been obtained from the director of health This necessitates a careful examination into the sanitary conditions of all existing cemeteries The cemetery question has long been a neglected one and this makes its regulation more difficult Many municipalities are establishing municipal cemeteries in which interments may be made without discrimination on account of race, nationality or religion

Vaccination in the Philippines.—In his report for the last quarter of 1906 Dr V G Heiser, chief quarantine officer, states that vaccination had to be temporarily abandoned in Antique because of a report that the people were being inoculated with the virus of leprosy, and in Occidental Negros, on account of a report that the people were being inoculated with cholera On the island of Luzon, particularly on the coast with the exception of a portion of Tayabas, Sorsogon and Iloilo provinces all the inhabitants have been protected As the travel is principally between coast cities, the danger of the spread of smallpox is considerably lessened This systematic scheme of vaccination has already borne results as attested by the fact that there is less smallpox in the Philippines to day than perhaps at any time during the past 300 years Whenever the vaccination of a province is completed the work is followed up by vaccinating at intervals of every six months all the children who have been born during that period, and all unvaccinated persons who may have taken up their residence there during the interim During the quarter covered in the report the work of vaccinating the inhabitants of Cebu was completed This is the first time in the history of the Philippines that the people of the entire province, numbering over three quarters of a million have been vaccinated The complete vaccination of the inhabitants of Union province was also terminated during the quarter A clinical note on this work appears in this issue, page 1204

CANADA.

Infectious Diseases.—The number of cases of infectious diseases in Montreal in March was 356 of which 101 were of tuberculosis—Over 1 000 residents of Three Rivers, Que, are reported to have typhoid fever, and the death rate is double the normal

Personal.—Dr I H Elliott has resigned from the Muskoka Cottage Sanatorium and has been succeeded by Dr W J Dobbie of the Western Free Consumption Hospital near Toronto Dr Elliott will spend several months abroad—Dr Henri Hervieux, Montreal, will succeed the late Sir William Hingston on the board of governors of Laval University

Hospital News.—The Canadian Hospital Association was organized in Toronto, April 1 Miss Louis Brent of the Sick Children's Hospital, Toronto was elected president, and Dr John N E Brown superintendent of the Toronto General Hospital, secretary Dr Renwick P Ross, Buffalo N Y delivered an address In connection with the Ontario hospitals, it was announced at this meeting that the government had

raised the grant 20 cents per patient per day—The Vancouver (B C) General Hospital will spend an additional \$20,000 on hospital equipment—The twentieth annual report of the board of management of the Protestant Hospital for the Insane at Verdun, Que, shows that on Jan 1, 1906, there were 503 patients in residence During the year there were admitted 87 men and 64 women The discharges numbered 110, and the deaths 31, leaving in the institution at the end of December 507 inmates

FOREIGN

International Congress of Physiotherapy.—As already mentioned in these columns on page 1195, the Second International Congress of Physiotherapy will be held at Rome, Italy, Oct 13-16, 1907, under the presidency of Hon Prof Guido Baccelli Prof Carlo Colombo, Via Plinio, 1, Rome, is the secretary The American committee has been appointed with Dr Francis B Bishop, Washington, D C, as president, and Dr William Benham Snow, 349 West Fifty seventh Street, New York, secretary

Plague in the Ottoman Empire.—Dr Post, American representative on the International Sanitary Board, reports that bubonic plague is on the increase at Djeddah, the port of Mecca When the first cases were reported great numbers of pilgrims were passing through Djeddah on their way to Mecca, and it was feared that the plague would break out among them A special meeting of the International Sanitary Board was called, and measures were taken to prevent its spread These were so successful that up to February 24 no case of plague had occurred among the pilgrims, over 100,000 in number

Morphin from Mail Order Houses.—The *Münch med Wochschr* relates that a Paris firm advertised in a German lay weekly that it would supply physicians and apothecaries "in discreet cases what they could not otherwise obtain" A German physician wrote to know if he could obtain morphin from the firm and received a prompt affirmative reply, with instructions as to the use of the morphin, "1 cg for one injection, and never more than three injections a day Internally 25 cg to begin with" The price charged was about \$1 for 15 grains As no order was forthcoming the firm wrote again to offer the morphin at half price The article adds that customers can order and receive morphin from the large French department stores

Bicentennial of Linnæus.—The scientific organizations of Sweden are making preparations to celebrate in the week of May 12 the two hundredth anniversary of the birthday of the great botanist, Carl von Linné, better known by his Latinized name, Linnæus As was mentioned recently in an editorial in THE JOURNAL, Linnæus was a physician, having taken a medical degree in the Netherlands in 1736, and four years later was appointed physician to the king of Sweden and professor of botany at Upsala He had published before this a work on the flora of Lapland, which he had explored under the auspices of the Swedish Academy of Sciences It was followed by numerous other works on botany which won for him the title of the father of systematic botany and of the binomial nomenclature of species The celebration of the bicentennial will be held at Upsala, where Linnæus lived, and where he died in 1778

Misuse of Names by Quacks.—A German "magnetopath," C Pohl, stated in the circulars he has been distributing, that Virchow came to him for treatment of a throat affection and was cured by him, giving the date and other particulars, and citing Virchow's expressions of confidence in his magnetic treatment The magnetopath was recently before the courts for fraudulent practices and was condemned to a fine of \$15 and 12 days' imprisonment In the course of the trial his lawyer referred to the Virchow incident and remarked that Dr H. Virchow Virchow's son, would confirm his client's statements in regard to the successful treatment of his father No notice was taken of the matter by the Virchow family, but Dr H. Virchow has since written a letter on the subject to the *Deutsche med Wochschr*, page 517, discussing the legal phases of this outrageous misuse of his father's name and whether the magnetopath or others like him could be prosecuted for such statements He seems to be inclined to think that the sentence imposed even if the charlatan were condemned, would not outbalance the advertising for the charlatan in case suit were brought against him The affair has three aspects, that bearing on his father, that on the interests of the public, and that bearing on the interests of the medical profession In regard to his father young Virchow thinks that no denial is needed from him The interests of the pro-

Disclaimer Concerning a Book on Fractures by Lamb

WASHINGTON, D C, March 28 1907
To the Editor —For the past two years the Postoffice Department here has been receiving every day or so letters addressed to 'Prof D K Lamb Curator National Medical Museum' and has been sending them to me for want of anybody else who comes anywhere near filling the bill There is no Prof D K Lamb in this city, and no institution of that name, nor am I curator of any museum These letters come from all parts of the country east of the Mississippi and they ask for a copy of the New Methods of Relieving Fractures and Dislocations I am unable to learn of any such book published here or distributed from here gratuitously as the applicants all evidently understand I have replied to a number of these letters but can not continue to do so

D S LAMB

Miscellany

Scarlet Fever Seven Times —This occurrence is reported by a Spanish writer cited in the *Munch med Wochschr*, liv 283 The first attack occurred at the age of 7 and the latest at 21 The disease is said to have been diagnosed by some of the best authorities in Spain each time

Case of Fatal Xerostomia —Zagari describes a case of dryness of the mouth from total absence of the salivary secretion owing to atrophy of all the maxillary, parotid and sublingual salivary glands The patient was a woman of 50 and she succumbed in less than two years to the marasmus resulting from lack of the secretions of the salivary glands Autopsy revealed a syphilitic or prapylitic lesion in the upper part of the oblongata He concludes that there must be at this point an anatomic nucleus presiding over the salivary glands and also over the sense of taste in the anterior two thirds of the tongue as function was abolished over this stretch in his case From this bulbo spinal center a neuron evidently passes through the chorda tympani to the salivary glands The histologic findings in the case are shown in several illustrations accompanying his communication in the *Policlinico* vii 45, 1907

Contagion of Leprosy —Since the establishment of the third leprosorium in Russia at Wenden 10 years ago it has sheltered 183 lepers Kiwull's report of its work is published in the *St Petersburg med Wochschr* for January 26 He mentions a number of instances of proved transmission of the disease In two cases the leprous wife infected her husband, in two the father his son in four the father his daughter, in four the mother one or more children and in one family the father with tubercular leprosy infected his brother, his sister and his four children In four cases a brother or sister became infected in contact with an inmate of the house Two patients ascribed their infection to having worn garments used previously by a leper and two other patients to washing the garments of a leper The tubercular form seemed more malignant than the other malar variety, both in regard to its course and to infection of others

Microscopic Examination of Endotheliomata of the Neck —Wirt Wingrave pathologist to the Central London Throat Hospital states that during the last year he has examined several growths belonging to the tumor described as endotheliomata removed from the cervical and parotid regions and from the upper respiratory and digestive tract The tumors he asserts may be defined as neoplasms developed from and following the type of epitheloid or mesothelioid cells such as are found lining blood and lymph vessels When starting from the lining of perivascular lymphatics they are called peritheliomata but if they start from the lining of the Rhin and Otol (London) there is a difference in the character of their element

fession in the struggle against unscrupulous quackery have compelled him to discuss the incident especially the lawyer's statement in the above case He is informed that the law does not require the lawyer to ascertain the truth of such assertions on his client's behalf, and remarks, "When a lawyer is legally allowed to shield his client by making such baseless statements, it would be very foolish for the charlatan not to profit by such a fortunate circumstance" It is possible that the charlatan will continue in the future the misuse of Virchow's name, as this matter had nothing to do with the sentence imposed and no steps have been taken to date to stop it

Twenty fifth Anniversary of the Discovery of the Tubercle Bacillus —On March 24 just 25 years had elapsed since Robert Koch reported the discovery of the tubercle bacillus in a communication read before the German Physiological Society In the *Deutsche med Wochschr* for March 21 Loeffler gives an interesting sketch of the occasion Koch had been called from his obscure post in a country district to Berlin just two years before, not long after his publications on mouse septicemia and anthrax had attracted general attention On arriving at Berlin, just 37 years old he met with a frosty reception from Virchow, and his announcements were criticised by Virchow's followers, especially in the local medical societies The Physiological Society however under the leadership of Dubois Reymond gave him unprejudiced attention and supplied certain facilities for his further research Consequently it was to that society that he turned when ready to publish his discovery on tuberculosis The hall was crowded to hear his communication "On Tuberculosis," although no hint of its importance had got abroad As he presented the array of facts which he had established every one present felt the importance of the occasion and not a word was spoken, not even when he had finished the session closing without a word of discussion The next day his demonstrations were thronged with scientists, including Virchow but it was years before the latter ever spoke of the bacillus except as "the so called tubercle bacillus" Koch's staining technic was an accidental discovery while he was seeking to photograph the bacilli He assumed that the blue stained bacilli would show better in a photograph if the whole specimen were stained further with Bismarck brown but examination of the specimens later showed that the bacilli still retained their blue tint when all else had turned brown He also found that this did not occur when a fresh solution of methylene blue had been used This suggested that some substance in the air must act on the blue solution as it stands, and he surmised that this might be ammonia as the air of a laboratory generally contains considerable ammonia A little ammonia added to the fresh solution of the blue made it act as he wished and he then assumed that any alkali would have the same effect This was the basis of the finally perfected stain

VIENNA LETTER

(From Our Regular Correspondent)

VIENNA, March 19, 1907

Sexual Problems in the Upper Schools

The movement for fighting venereal diseases by public instruction has called attention to the fact that numerous sexual infections take place simply from ignorance of the danger and of the means of prevention Thus in German speaking countries the university students at once, on entering the 'alma mater' come under influences of free thinking and unscrupulous circles, and the contrast between the strict supervision in the preparatory schools and the absolute liberty in the university tends to turn the attention of the young men to sexual matters with the result that 30 per cent of all gonorrheal and 25 per cent of all syphilitic primary infections occur between the ages of 20 and 22 when in our countries the youths enter the university In a few of the preparatory schools the pupils during the last term are now instructed in the facts of sexual dangers Another important achievement of the recent movement in which several professors of the university are interested is the 'Instructions Blatt' a leaflet explaining in a few words the chief symptoms of sexual diseases and warning against treatment by quacks and secret remedies This leaflet is handed to the young laborers and factory hands, to students on matriculating and to the scholars of the trade schools on leaving

The Economic Cost of Epilepsy —The ultimate cost to the state of epileptics at large can not be estimated but it is enormous —H T Patrick MD in *Charities and the Commons*

loosely termed "adenosarcoma," "atypical carcinoma," "mixed sarcoma," but Wingrave states that on looking over old preparations he would now unhesitatingly describe them as endotheliomata. The tumors may originate either from the epitheloid lining of vascular channels, blood and lymphatic (endotheliomata), or that surrounding the vessels (peritheliomata). Cytologically, there is no difference, but the spreading and grouping of the essential elements are somewhat different. The tumors are also said to arise in vestigial structures, such as occur in connection with the branchial clefts on and in the intercarotid gland, probably from angioblastic elements. In structure, they are usually firmly encapsulated. The stroma is well marked, either fibrillated or homogeneous, forming spaces of varying size. Cells when present are elongated, fusiform and closely packed, sometimes encapsulated, giving the appearance of cartilage. The matrix contains mucigen or collagen. The essential endothelial elements are cells which, though varying in size and shape, always possess the characteristic of the epitheloid or mesothelial cells, viz., large oval nuclei, having a fine close chromatin network and staining faintly with hemalum. The cytoplasm is abundant and very finely granular or clear. The cells may be columnar, spheroidal, flattened or fusiform. Very rarely they are laminated, forming pearls like ordinary squamous epithelium, from which they may be easily distinguished. Heteromitoses are not common neither is lymphocytosis with wandering chromosomes—features so characteristic of epitheliomata.

Electricity Barred from Turkish Hospitals.—H. Paul of Carlsruhe writes entertainingly in the *Deutsche med. Wochenschr.* February 28, of a trip in the eastern Mediterranean. He states that the Sultan is convinced that electric lights, electric tram cars, telephones, etc., are devices of the evil one, and that he has strictly forbidden their use throughout his dominions. This deprives the hospitals of radiology and electrodiagnosis, etc. In the Turkish hospitals, besides, the thermometer is regarded as superfluous. Dr. Devcke, formerly of Hamburg, is in charge of the Gülhane Hospital at Constantinople, and by great diplomacy and tact he secured permission to use electricity in this hospital. Not long ago he received orders from the Sultan to vacate the hospital entirely and to remove all the inmates and equipment, as the Sultan wanted to attend the great mosque near by and did not wish to be disturbed by the presence of the sick and of the diabolical electric machines so near him. Again the sturdy German's diplomacy brought him successfully through this crisis, but the hospital suffers constantly from an utter lack of funds to maintain it properly. In Greece, on the other hand, Paul says, the hospitals are equipped and maintained on a level with the standard of western civilization; even rubber gloves are not wanting. He comments on the immense number of bladder stones preserved in the hospital at Smyrna. The composition of the water is locally regarded as the cause of this tendency to bladder stones. [This traveler's experience seems not in accord with the reports of the Constantinople correspondent of the *London Lancet*. The latter gives the impression that a large proportion of Turkish hospitals are pretty fairly equipped with modern appliances.]

Association News

HALF FARE TO ATLANTIC CITY

One Fare for Round Trip to the Annual Session of the American Medical Association.

The New England Passenger Association, the Trunk Line Association and the Central Passenger Association have granted a rate for the round trip of one first class limited fare plus \$1. Tickets will be good going June 1 to 4, inclusive, returning leaving Atlantic City June 4 to 10, inclusive. By deposit of the ticket by the original purchaser in person with the special agent at Atlantic City not later than June 10, and payment of fee of \$1 at time of deposit an extension of the return limit may be obtained to leave Atlantic City not later than June 14.

Thus far the Western Passenger Association has granted only a rate of one and one third fare for the round trip, but the matter has been taken under further consideration and

it is hoped that a half fare rate will be secured in the territory covered by this association also.

The Transcontinental Passenger Association has granted a one first class 30 day fare for the round trip, tickets to be on sale May 20 and 21. Final arrangements of this association with the eastern passenger associations have not yet been made. The Transcontinental Passenger Association covers the western part of the United States, including all of the Pacific Coast.

BOOKS ON URANALYSIS

DREKA CAL. March 20 1907

To the Editor—Please name a text book on uranalysis that explains the clinical significance and method of determination of total nitrogen urea nitrogen and ammonia nitrogen in urine—the nitrogen partition. Will you also give a ready and rapid method for determining the (1) total nitrogen (2) the nitrogen as urea and (3) the ammonia nitrogen the ammonia coefficient?

JOHN J GANNON MD

ANSWER—The following text books give the methods of determining the total nitrogen and contain discussions in regard to the distribution of the urinary nitrogen in urea ammonia and other nitrogenous compounds. Boston's Clinical Diagnosis Croftan's Clinical Urinology v Jaksch's Clinical Diagnosis and most text books on physiologic chemistry.

The best method of determining the total nitrogen is that of Kjeldahl as it enables the operator to perform a number of determinations at the same time. If the necessary apparatus is once properly installed the method is rapid. The method is based on the following principle (quoted from Croftan). The nitrogenous constituents of the urine on boiling with concentrated sulphuric acid are destroyed and all the nitrogen that is not in direct combination with oxygen is converted into ammonia the latter combines with the sulphuric acid and goes into solution as sulphate of ammonia. The bodies that contain nitrogen in direct combination with oxygen are present in such small quantities (and occasionally not all) that they may be neglected for practical purposes. The acid solution of ammonium sulphate is treated with hot soda lye and the ammonium thus liberated caught in a measured quantity of normal acid and the excess of acid titrated back from the amount of ammonia formed the nitrogen of the urine can readily be calculated. The quickest clinical method for determining the urea nitrogen is the hypobromite method of Hufner (Knop). The apparatus required for this determination is simple and the method is rapid of execution. It is based on the principle that sodium hypobromite in alkaline solution decomposes urea into nitrogen carbon dioxide and water. The carbon dioxide that develops is absorbed by the alkali line solution (soda lye) while the nitrogen passing through this solution can be caught in a suitable measuring apparatus and thus determined. The ordinary Doremus apparatus is constructed on principles similar to the Hufner apparatus however for estimating the ammonia coefficient or for any clinical work that is even remotely expected to approach accuracy the apparatus of Doremus is quite useless.

The ammonia of the urine is as a rule determined according to the method of Schloesing this is not the most accurate method but it is the simplest and the quickest of execution and generally suffices for clinical purposes. It is based on the following principle. If the urine is treated with lime water most of the ammonia it contains is released from its combinations with other radicles. If the urine containing the lime water is placed under a glass jar with a dish of concentrated sulphuric acid then the liberated ammonia will be caught by the latter and the degree to which the sulphuric acid has been neutralized by the ammonia after 24 or 48 hours can then be determined by titration. As a rule the direct determination of the ammonia is not performed but the total so called ammonia nitrogen of the urine and this includes the nitrogen bound in substituted ammonia (amino and amido etc compounds) radicles. This ammonia nitrogen is determined from the difference between the total urinary nitrogen and the urea nitrogen for the bulk of the nitrogen that is not combined as urea is present in the urine in the form of substituted ammonia compounds.

CUBAN ITCH

FRANKSON Ohio March 21 1907

To the Editor—There have been local reports of a condition styled Cuban Itch. I have failed to see references to it in Journals. If such a condition exist what are its characteristics? If not what malady I being confused? W J THATCHER

ANSWER—After the Spanish American war in 1898 an epidemic of smallpox of a very mild character prevailed extensively throughout the northern United States. By many this epidemic was attributed probably correctly to the introduction of the disease returned soldiers from Cuba and the Philippines. It has been in consequence of the mildness of the disease was not recognized and it was variously called Philippine measles etc. While the cause of the epidemic is probably the same term has been applied to exanthemata and to other forms of skin disease.

SOLUTION OF CELLULOSE

OCALA FLA March 28 1907

To the Editor—Kindly give formula for ammoniated copper solution which is used for making a solution of cellulose. Yours very truly
W H POWERS, M.D.

ANSWER—Ammoniated copper solution or Schweltzer's reagent was formerly prepared by leaving copper turnings partially immersed in ammonia with access of air but it is better made by precipitating copper hydroxide from a cold solution of copper sulphate by adding an excess of caustic soda. The well washed precipitate is then dissolved to saturation with ammonia. On treatment with the resultant solution cellulose becomes gelatinous and on agitation gradually dissolves forming a viscid solution which may be filtered after dilution with water.

TARTARILITHINE

MEMPHIS TENN

To the Editor—I enclose an ad of Tartarilithine from the inside cover of the *Literary Digest*. It speaks for itself. It has been my impression heretofore that McKesson & Robbins conducted an ethical business. Certainly they have advertised Tartarilithine extensively to physicians.

LOUIS LEROY

LOMA LINDA CAL.

To the Editor—Can you tell me the composition of Tartarilithine, advertised to the laity by McKesson & Robbins? What is there in it which would check the discharges of postnasal catarrh?

GEORGE K. ABBOTT

ANSWER—The two letters quoted are specimens of several received on the same subject during the last few months. We have had Tartarilithine examined by two chemists whose reports indicate that it is an effervescent preparation composed of approximately 20 per cent of carbonate of lithium and about 80 per cent of tartaric acid. Thus it is simply another of the hundreds of lithia preparations on the market offered for the cure of rheumatism. This in spite of the fact that scientific investigation and clinical experience have demonstrated that lithia is of very little if any use in that disease. While the advertisement carries the idea that Tartarilithine is a product of the Tartarilithine Company and that McKesson & Robbins are simply the selling agents we are informed that the business is owned by McKesson & Robbins who under this style manufacture a remedy for rheumatism. In regard to the information asked for by our correspondents we would suggest that they write to McKesson & Robbins who will undoubtedly gladly reply. We would especially suggest to Dr. Abbott that he ask the firm how a mixture of lithia and tartaric acid will check the discharges of postnasal catarrh.

THE BIOCHEMICAL JOURNAL

DENVER March 30 1907

To the Editor—Please inform me who are the publishers of the *Biochemical Journal* and tell me if possible the cost of a single copy.

BERNARD OETTINGER M.D.

ANSWER—The *Biochemical Journal* is published by the Biochemical Department Johnston Laboratories University of Liverpool England. The American agent is G. E. Stecher, 129 West Twentieth Street New York City. This is a new journal only in its second year and not as yet very widely distributed. The cost of each is no varies with the size of such issue.

The Public Service

Army Changes.

Memorandum of Changes of stations and duties of medical officers U. S. Army week ending April 6 1907.

Borden Wm. C. surgeon granted three months leave of absence to take effect about June 15.

Killbourne E. D. asst. surgeon relieved from duty at General Hospital Presidio San Francisco and ordered to Fort Brady Mich. Talbott E. M. asst. surgeon ordered to proceed from Fort Leavenworth Kans. to Fort Oglethorpe Ga. for duty with the Second Squadron 12th Cavalry at that post for duty to accompany command to the Jamestown Ter-Centennial Exposition.

Jordan Wm. C. surgeon relieved from duty at General Hospital Washington Barracks D. C. to take effect on expiration of leave of absence and will then proceed to Manila, P. I. for duty.

Munson E. L. surgeon relieved from duty at General Hospital Fort Bayard N. M. and ordered to Fort Sheridan Ill. for duty.

Rockhill E. P. asst. surgeon relieved from treatment at Army General Hospital Presidio of San Francisco and will proceed to General Hospital Fort Bayard N. M. for observation and treatment.

Crosby Wm. D. surgeon relieved from duty at Vancouver Barracks Washington and ordered to the U. S. Soldiers Home Washington D. C. as attending surgeon, and will report about June 14 1907.

Arthur Wm. H. surgeon relieved from duty as attending surgeon U. S. Soldiers Home Washington D. C. and will proceed to Washington Barracks D. C. and assume command of the General Hospital at that post on June 15.

Moyle J. P. asst. surgeon general granted leave of absence for one month and twenty five days.

Heard George P. asst. surgeon detailed as a member of the Army

retiring board to meet at Denver, vice Col. E. B. Mosely asst. surgeon general hereby relieved.

Snyder C. R. asst. surgeon is relieved from duty in the Philippines Division to take effect at such time as will enable him to comply with order and will proceed by first available transport sailing from Manila after June 1 1907 to San Francisco and on arrival will report by telegraph to the Adjutant General of the Army for further orders.

Sweazey V. E. asst. surgeon will render the necessary attendance at Fort Irbie Me. during the absence of Contract Surgeon Whitner at Fort McKinley Me.

Hart James W. contract surgeon ordered to accompany troops from Washington Barracks D. C. to target Camp Annapolis Md. and remain on duty at that camp.

Wall F. M. contract surgeon granted sick leave of absence for two months.

Tyler George T. contract surgeon relieved from duty at Fort Monroe Va. and ordered to West Point N. Y. for duty.

Pomeroy John L. contract surgeon ordered from New York to Fort Wright, Wash. for duty.

Navy Changes

Changes in the Medical Corps U. S. N. for the week ending April 6 1907.

Jones E. L. asst. surgeon, detached Medical School Washington D. C. April 3 and ordered to Naval Hospital Mare Island Cal. May 20.

Robnett A. H. asst. surgeon detached from Medical School April 3 to Naval Station San Juan.

Lee, A. E. asst. surgeon, to Naval Medical School Washington, D. C.

Allen A. H. asst. surgeon detached Medical School April 3 to duty with Marines at Camp Columbia Cuba.

Kuder W. S., asst. surgeon detached Medical School April 3 ordered to Minnesota.

Havnes J. I. asst. surgeon detached Medical School April 3 ordered to the Virginia.

Ransdell R. C. asst. surgeon detached Medical School, April 3 ordered to the Maine.

Ames M. H. asst. surgeon detached Medical School, April 3 ordered to the *U. S. Jersey*.

Kaufman J. B. asst. surgeon detached Medical School ordered to the Tennessee.

Smith H. L. acting asst. surgeon detached Medical School, April 3 to Naval Recruiting Station, Omaha Neb.

Steadman W. G., acting asst. surgeon detached Medical School April 3 ordered to Naval Recruiting Station Providence, R. I.

Baker M. C. acting asst. surgeon detached Medical School April 3 to Navy Yard Norfolk, Va.

Longabaugh R. I. acting asst. surgeon detached Medical School April 3 to Annapolis Hospital.

Huff, E. P. acting asst. surgeon detached Medical School April 3 to Proving Grounds Indian Head, Md.

Donaldson M. acting asst. surgeon detached Medical School, April 3 to Naval Recruiting Party No. 3.

Minter J. M. asst. surgeon from Medical School to Guam Station.

Cohn I. F. Ralston T. W. Winn C. K. Downey J. O. Butts, H. from school to Asiatic Station.

Flint J. asst. surgeon from Medical School to Sannaco Hospital.

Dollard, H. L. acting asst. surgeon from school to Newport Hospital.

Odell H. F. surgeon from Newport Hospital, to Naval Hospital Washington D. C. and to duty on course of instruction at the U. S. Naval Medical School.

Carton W. M. surgeon detached from Naval Hospital Washington D. C. ordered home 2 weeks leave thence to Ohio.

Moore, J. M. surgeon detached Norfolk Hospital to Naval Recruiting Station, Minneapolis Minn.

Plummer R. W. P. A. surgeon detached Naval Recruiting Station Chicago Ill. to duty on course of instruction at the U. S. Naval Medical School Washington D. C.

Baker W. W. P. A. surgeon detached Naval Hospital New York to Naval Hospital Portsmouth N. H.

Freeman G. F. P. A. surgeon detached Naval Hospital Portsmouth N. H. to duty in attendance on course of instruction at the U. S. Naval Medical School Washington D. C.

McLean W. T. asst. surgeon detached from Navy Yard Boston Mass. to Naval Recruiting Station Chicago.

Miller J. T. acting asst. surgeon detached from Naval Recruiting Station Minneapolis Minn. to course of instruction at Naval Medical School Washington D. C.

Balch A. W. P. A. surgeon detached Naval Medical School Washington D. C. April 5 ordered to Naval Hospital Cavite P. I. sailing from New York N. Y. April 20 stopping en route at London England Hamburg Germany and other points for special duty.

Tolfree H. M. P. A. surgeon detached from the Connecticut to the Dolphin.

McDonald P. E. asst. surgeon detached Dolphin to the Connecticut.

Baker M. W., P. A. surgeon detached Naval Hospital New York N. Y. to Naval Hospital Boston.

Public Health and Marine Hospital Service.

List of changes of station and duties of commissioned and non-commissioned officers of the Public Health and Marine-Hospital Service for the seven days ended April 7 1906.

Proctor S. D. surgeon relieved from duty at San Diego Cal. and directed to proceed to Los Angeles and to assume charge of the service at that port relieving Surgeon J. O. Cobb.

Cobb J. O., surgeon relieved from duty at Los Angeles and directed to proceed to Cairo Ill. and to assume command of the service at that port relieving Surgeon G. M. Calver.

Calver G. M. surgeon relieved from duty at Cairo Ill. and directed to proceed to Mobile Ala. and to assume command of the service at that port relieving J. A. Surgeon Edward Francis.

von Fzdorf I. H., P. A. surgeon assumed command of New Orleans Quarantine Station April 1 1907.

Fox Carroll P A surgeon leave of absence granted Dec. 28, 1900 for 14 days revoked

Francis Edward P A, surgeon relieved from duty at the Marine-Hospital Mobile Ala. and directed to assume command of the Quarantine Service at that port April 1 1907

Robertson E McG Asst surgeon relieved from duty at Philadelphia and directed to proceed to Reedy Island Quarantine Station reporting to the medical officer in command for duty and assignment to quarters

Salmon T W asst surgeon granted leave of absence for 4 days on account of sickness from March 23 1907

de Vallin Hugh asst surgeon relieved from duty at Reedy Island Quarantine Station and directed to proceed to New Orleans Quarantine Station reporting to the medical officer in command for duty and assignment to quarters

Jackson J M Jr acting asst. surgeon granted leave of absence for 10 days from March 27 1907

McCormac, J T acting asst. surgeon granted leave of absence for 30 days on account of sickness from Feb 9 1907

McConnell F I acting asst surgeon department letter of Feb 26 1907 amended so as to grant acting asst surgeon McConnell 22 days leave of absence from Feb 25 1907 instead of 30 days

Safford M V acting asst surgeon directed to proceed from Boston to Westborough Mass for special temporary duty on completion of which to rejoin his station

Story H C acting asst surgeon granted leave of absence for 30 days from May 1 1907

BOARDS CONVENED

A board of medical officers was convened to meet at Philadelphia April 4 1907 for the physical examination of an officer of the Revenue-Cutter Service Detail for the board Surgeon J M Gassaway chairman P A, Surgeon T Clark recorder

A board of medical officers was convened to meet at Wilmington N C April 8 1907 for the physical examination of an officer of the Revenue Cutter Service. Detail for the board P A Surgeon C H Lavinder chairman

Health Reports

The following cases of smallpox, yellow fever, cholera and plague have been reported to the Surgeon General Public Health and Marine-Hospital Service during the week ended April 5 1907

SMALLPOX—UNITED STATES

California San Francisco March 16-23 2 cases

Marriages

SAMUEL STINER M D, to Miss Rebecca E Kilham both of Philadelphia, March 24

WILLIAM JOHN MALLOY, M.D, to Miss May Hanley, both of Muncie, Ind., recently

ROBERT M MILLER M D to Miss Lena Jenks, both of Bogard, Mo, March 20

FREDERIC KAMMERER, M.D to Miss Ida Knapp both of New York City, March 23

ROBERT C BRADLEY M D to Miss Charlotte Marie Perkins both of Peoria, Ill, March 30

LEANDER HOWARD SHEARER M D, to Miss Grace T Parler, both of New York City, April 6

JAMES ROBERTSON DAWSON, M.D, to Miss Theresa Musher both of Birmingham, Ala., April 3

EDWARD GILLETTE MARTIN, M.D, Detroit, Mich., to Miss Helen Marian Fraser of Petrolia, Ont, March 27

Deaths

Frank Swartzlander, M.D University of Pennsylvania, Department of Medicine, Philadelphia 1863, in 1862 anatomist of the Military Hospital Philadelphia, where he made all the postmortem examinations until his graduation a year later in March, 1863, appointed assistant surgeon of the Seventy-fourth Pennsylvania Volunteer Infantry, chief surgeon of the field hospital of the Third Division, Eleventh Army Corps, at the battle of Gettysburg later assistant surgeon of volunteers and in charge of the auxiliary military hospital at Savannah Ga., dean of the medical profession of Docketstown Pa a member of the state and county medical societies died suddenly at his home, March 31 from acute gastritis, aged 67

Joseph Gilbert Bemas, M.D College of Physicians and Surgeons in the City of New York 1865, Bennett College of Eclectic Medicine and Surgery, Chicago 1883 a member of the American Medical Association, assistant surgeon of the First Minnesota Volunteer Infantry during the Civil War a practitioner of Chicago for 24 years, died at his home in that city April 1, from tuberculosis, after an illness of four months, aged 62

William Henry Drummond, M.D University of Bishop College, Faculty of Medicine Montreal 1884, famous for his poems on the French Canadian habitants, professor of medical jurisprudence at Bishop College and a prominent practitioner of Montreal died in Cobalt Ont., where he was manager of the Drummond mine from cerebral hemorrhage, April 6 after an illness of five days, aged 51

William Oglesby Sweeney, M.D Bellevue Hospital Medical College, New York City, 1864 one of the oldest and most prominent practitioners of Lexington Ky and for a number of years instructor in chemistry at Hooper College who retired from practice 20 years ago on account of blindness died at his home in Lexington, March 27, after a prolonged illness aged 60

Lewis L Pollock, M.D University of Maryland School of Medicine Baltimore 1856 a surgeon in the Confederate service during the Civil War thereafter a practitioner in Boston and for the last 18 years a resident of East Weymouth Mass died in Bellevue Hospital New York City March 27 from gastritis after an illness of one week, aged 70

Alfred George Mays, M.D University of Michigan Department of Medicine and Surgery, Ann Arbor, 1878 for 27 years a prominent practitioner of Leadville Col Cliff and Victor Colo who moved to Nevada City Cal on account of his health last year died in that city from cerebral hemorrhage March 3 after an illness of two days aged 75

Nicholas Lafayette Campbell, M.D College of Physicians and Surgeons in the City of New York 1845 one of the founders of the New York Academy of Medicine in 1847 a veteran medical officer of the Mexican and Civil wars and his retirement a clerk in the health department of New York City died in that city March 29 aged 84

George Warren Barlow M.D College of Physicians and Surgeons in the City of New York 1873 a member of the American Medical Association and a veteran of the Civil War during which he served in the Fifteenth New Jersey Volunteer Infantry died at his home in Three Bridge N J March 28 from paralysis aged 63

William J. Wroth, M.D. University of Maryland School of Medicine, Baltimore, 1852, for a number of years resident physician of the Marine Hospital, Baltimore, and founder of the Rush Medical Club at the University of Maryland died at his home in Baltimore, April 3, from intestinal obstruction, after a short illness, aged 77.

Clarence Edward Avery Buckley, M.D. Halifax Medical College, Medical Faculty of Dalhousie University, Halifax, N. S., 1904, formerly interne at the Victoria General Hospital, and then a practitioner at Thorburn, died at the residence of his father in Halifax, March 27, from tuberculosis, after a prolonged illness, aged 24.

Thomas Wight, M.D. College of Physicians and Surgeons in the City of New York, 1864, a member of the state and county medical societies, and one of the oldest practicing physicians of Delaware County, N. Y., died at his home in Andes, March 31, from injuries sustained in a runaway accident three days before, aged 73.

Allen Castle Simonton, M.D. Northwestern University Medical School, Chicago, 1865, a veteran of the Civil War, a resident of Washington since 1870, and for several years chief surgeon of the Great Northern System, died at his home in Seattle, March 26, from heart disease, after an illness of two years, aged 60.

Young A. Matthews, M.D. Shelby Medical College, Nashville, Tenn., 1859, president of the Cass County (Texas) Medical Society, who served throughout the Civil War as surgeon of the Eighteenth Texas Infantry, C. S. A., died at his home in Atlanta, Texas, Nov. 20, 1906 from heart disease, aged 69.

Samuel R. Richardson, M.D. Medical Department, Victoria College, Toronto, 1871, coroner of York County, Ontario, for several years, and for more than 30 years a practitioner of Eglinton, died in North Toronto, March 20, from pneumonia complicating typhoid fever, after a long illness, aged 64.

Robert Stuart MacGregor, M.D. New York University Medical College, 1897, a member of the state and county medical societies, and a member of the staff of St. Bartholomew's Clinic and of the New York Polyclinic, died at his home in New York City, March 23 from pneumonia, aged 38.

George W. Pettit, M.D. Cleveland Medical College, Medical Department of Western Reserve Medical College, 1863, said to have been the oldest practitioner of Mahoning County, Ohio, died at his home in Petersburg, March 8, from concussion of the brain, due to a fall four days before, aged 79.

Guido Spitz, M.D. Faculty of Medicine, Paris, France, 1870, who saw service under the English government in Egypt and India, but for the last three years and a half has been in practice at Los Banos, Cal., died at his home March 15, from tuberculosis after a prolonged illness, aged 60.

Harry E. Burdett, M.D. Faculty of Medicine of Queen's University and Royal College of Physicians and Surgeons, Kingston, Ont., 1886, for 20 years a practitioner of St. Paul, Minn., died in a hospital in that city, March 27, from heart disease, after an illness of several weeks, aged 45.

Mitchell Starr, M.D. Starling Medical College, Columbus, Ohio, 1863, assistant surgeon of the Seventy-fourth Ohio Volunteer Infantry throughout the Civil War and one of the oldest practitioners of Van Wert County, Ohio, died at his home in Shenandoah, March 27, aged 86.

John B. Callan, M.D. Chattanooga (Tenn.) Medical College, Medical Department of Grant University, 1905, a promising young physician of De Kalb County, formerly a practitioner of Bridgeport, Jackson County, Tenn., died in New Mexico, from tuberculosis, March 23.

Robert Colman Arnette, M.D. Louisville (Ky.) Medical College, 1873, a veteran of the Civil War in the Confederate service and a practitioner of Monticello, S. C., died at the residence of his brother in law, near Ridgewood, S. C., March 20 from nephritis, aged 59.

George W. Matthews, M.D. Medical Department of the University of Louisiana, New Orleans, 1872, a veteran of the Mexican War, and a member of the Texas legislature in 1875 died at his home in Garden Valley, Texas, March 28, from influenza, aged 80.

Charles F. Reilly, M.D. College of Physicians and Surgeons, Baltimore 1902 of Woonsocket, R. I., school committeeman of the town of Blackstone, R. I., died at the home of his parents in that city, March 31, after an illness of several weeks, aged 34.

Florentine O. Reeve, M.D. Cleveland University of Medicine and Surgery, 1894, for some time a professor in his alma mater and superintendent of schools of Brooklyn, Ohio, died at his home in Cleveland, March 29, from pneumonia, aged 55.

James E. O'Malley, M.D. New York University Medical College, 1888, a member of the staff of St. Luke's Hospital, Newburgh, N. Y., died at his home in that city, after a long illness, consequent on a fall several years ago, March 27, aged 46.

John W. Stoner, M.D. Cleveland University of Medicine and Surgery, 1888, secretary of the board of education and board of health of North Baltimore, Ohio, died in a hospital in Cleveland after an operation for cancer, March 22, aged 47.

Frances Van Cleve Fuller, M.D. Woman's Medical College of the New York Infirmary, New York City, 1884, a retired practitioner of Brooklyn, died at her residence in that city, March 27, from pneumonia, after a short illness, aged 56.

D. David Fisher, M.D. University of Vermont College of Medicine, Burlington, 1883, for the last eight years justice of the peace, died at his home in Kersey, Pa., March 24, from heart disease after an illness of two weeks, aged 50.

James Fletcher Winsell, M.D. Ohio Medical College, Cincinnati, who had retired from practice more than 25 years ago, died in Redding, Cal., Nov. 9, 1906, from paralysis, after an illness of five days, aged 81.

John W. Culley, M.D. University of Michigan, Department of Medicine and Surgery, Ann Arbor, 1873, died at his home in Salt Lake City, Utah, March 21, from pneumonia, after a short illness, aged 67.

William McCallum, M.D. College of Physicians and Surgeons of Chicago, 1886, for many years a practitioner of Gladstone, Mich., died at the Northwestern Hospital, Minneapolis, Minn., March 28, aged 52.

Berry Meek, M.D. St. Louis Medical College, 1857, a pioneer physician of Holt County, Mo., died at State Hospital No. 2, St. Joseph, where he had been an inmate for nearly ten years, March 27, aged 80.

Lawrence F. Berry, M.D. Jefferson Medical College, Philadelphia, 1905, an interne at the Philadelphia Hospital, died at that institution from erysipelas, March 29, after an illness of five days, aged 25.

Samuel D. Bickel, M.D. University of Pennsylvania, Department of Medicine, Philadelphia, 1895, at one time warden of the Atlantic County prison, died at his home in Atlantic City, N. J., March 26.

Robert Fuller Eubank, M.D. Baltimore Medical College, 1890, of Ottoman, Lancaster County, Va., a member of the state and county medical societies, died March 26, after a brief illness, aged 42.

William H. Dwight, M.D. College of Medicine, Syracuse (N. Y.) University, 1876, cashier of the State Bank of Goddard, Kan., was found dead from gunshot wound, a mile east of Goddard, April 3.

John Mattauer Winfree, M.D. Medical College of Virginia, Richmond, 1889, of Richmond, Va., died at the home of his father in law in Raleigh, N. C., March 31, after an illness of two years.

Ethelda M. Teeters Widemann, M.D. University of Wooster, Medical Department, Cleveland, 1895, died at her home in Cleveland, Ohio, from septicemia, after an illness of one week, aged 35.

William R. Stout, M.D. Kentucky School of Medicine, Louisville, 1881, formerly a practitioner of Covington, Ind., died at his home near North Vernon, Ind., March 16, after a prolonged illness.

George G. Ware, M.D. Jefferson Medical College, Philadelphia, 1857, died at his home in Stanton, Tenn., March 25, from injuries received in a runaway accident several days before.

Francis E. Watts, M.D. Hahnemann Medical College and Hospital, Chicago, 1883, died at his home in Olean, N. Y., March 27, from hemorrhage of the lungs, after a short illness, aged 47.

Ernest S. Empey, M.D. College of Medicine of the University of Nebraska, Omaha, 1905, formerly of Torrington, Wyo., died at his home in Scott's Bluff, Neb., January 28, from tuberculosis.

George H. Duncan, M.D. McGill University Medical Faculty, Montreal, 1892, for some time a practitioner of the Yukon, died at his home in Victoria, B. C., Dec. 2, 1906, aged 44.

Louis N. Hilleary, M.D. New York University Medical College, New York City, 1880, formerly a practitioner of Burlington, Iowa, died at his home in Poway, Cal., aged 54.

Lewis U. Singer, M.D. Jefferson Medical College, Philadelphia, 1881, one of the first settlers of Clearfield, Iowa, died at his home in that place, from pneumonia, March 25.

Joseph N Knight, M.D. Boston University School of Medicine, 1883, died at his home in Chiffondale Mass., March 30, from tuberculosis, after an illness of a year, aged 45

James S Sullivan, M.D. Medical School of Harvard University, Boston, 1804, died at his home in Randolph, Mass., March 23, from pneumonia, after a brief illness, aged 41

Henry B Evarts, M.D. Eclectic Medical Institute, Cincinnati, 1871, died at his home in Grand Rapids, Mich., March 31, after an illness of two days, aged 61

Floyd Clendenen, M.D. Bennett College of Eclectic Medicine and Surgery, Chicago, 1874, died at his home in La Salle, Ill., April 4, from pneumonia, aged 69

John MacDonald, M.D. Jefferson Medical College, Philadelphia, 1879, died at his home in Chatham, N. B., Dec. 12, 1900, after a long illness, aged 55

John Munro Campbell, M.D. McGill University Medical Faculty, Montreal, 1860, died at his home in Greenpoint, Brooklyn, N. Y., April 2, aged 70

Joel Y Lynch, M.D. Indiana Eclectic Medical College, Indianapolis, 1887, died at his home in Rosedale, Ind., April 2, after a long illness, aged 55

Thomas A Skillman, M.D. New York University Medical College, New York City, 1878, died at his home in New Brunswick, N. J., aged 53

Warren F Barksdale, M.D. University of Louisville Medical Department, 1855, died at the home of his daughter in Hardy, Miss., March 9, aged 77

Frank Riley, M.D. St. Joseph (Mo.) Medical College, 1882, died suddenly at his home in St. Joseph, April 1, from cerebral hemorrhage, aged 48

Jasper N Taylor, M.D. Vanderbilt University, Medical Department Nashville, Tenn., 1871, died at his home in Lynchburg, Tenn., March 27

Belton O Bennett, M.D. Medical College of the State of South Carolina, Charleston, 1876, died at his home in Greer's, S. C., January 17

John Batemen Deere, M.D. Memphis Hospital Medical College, 1898, of Sandy Springs, Ark., died in Little Rock recently, aged 39

Robert Farnes, M.D. Long Island College Hospital, Brooklyn, 1865, died at his home in New York City, March 31, aged 72

William E Pillsbury, M.D. Dartmouth Medical School Hanover, 1873, died at his home in Milton Mills N. H., February 10

G. A. L. Payne, M.D. McGill University Medical Faculty, Montreal, 1906, died at Montreal in January, from typhoid fever

William C Christian, M.D. St. Louis Medical College, 1865, died recently at his home in New Bloomfield, Mo., aged 76

Samuel Clarke, M.D. Jefferson Medical College, Philadelphia, 1899, died at his home in Philadelphia, March 29

Deaths Abroad

F. J. Herrgott, M.D., professor of obstetrics at Nancy since 1872, died March 5 aged 93. Besides his numerous publications on gynecologic, obstetric and surgical subjects, he wrote a history of obstetrics, translating Siebold's work and bringing the history down to date. In his eighty-third year he published a translation of the celebrated treatise on diseases of women by Soranus of Ephesus. Herrgott also published a work entitled "The Chamberlin Family and the Discovery of the Forceps." He is said to have been the first physician who systematically made a practice of watching over the health of infants born in his service giving each mother a louis (\$4) out of his own pocket when she had raised a healthy infant following his directions.

A. von Weismayr, M.D., first director of the great Alland sanatorium in Austria but for the last few years chief of a Vienna hospital one of the collaborators on the *Wien Klin. Wochenschau* died March 12 aged about 40. He was the first medical man in Austria to devote his efforts and research exclusively to the question of tuberculosis and his popular pamphlet "The Essence of Tuberculosis" has been distributed by thousands. He succumbed a victim to the disease to which he had devoted his life. An article from his pen on the prognosis of tuberculosis is still appearing in serial form in the *Rundschau*.

A. Petraglia, M.D. dean of the physicians at Rome Italy died March 10 aged 91

Medical Economics

THIS DEPARTMENT EMBODIES THE SUBJECTS OF ORGANIZATION CONTRACT PRACTICE INSURANCE FEES MEDICAL LEGISLATION ETC

A Move in the Right Direction

A bill of more than ordinary importance has been introduced into the General Assembly of the state of New York by Mr. Merritt. It is entitled, "An act to provide for holding a convention within the state of New York of delegates to be appointed by the governors of the several states for the purpose of devising and recommending to the legislatures thereof uniform laws, and making an appropriation therefor." The bill, which is a short one, authorizes the governor of the state of New York to appoint three delegates and to invite the governor of each other state in the union to do the same. These delegates are to meet during the coming October at some place in the state of New York and are to consider and recommend to their respective legislatures the enactment of uniform laws in the matter of life and fire insurance, divorce, labor, public utilities, etc. The expense of holding this convention and also the actual traveling expenses of the various delegates will be paid by the state of New York, and the bill calls for an appropriation for this purpose.

It is to be hoped that this bill will become a law and that the convention provided for therein may be held. Among the subjects that may well be considered by the convention is the examination and licensing of physicians and the regulation of the practice of medicine. Under the federal Constitution such matters as those enumerated in the bill come under the head of functions not surrendered by the states to the general government. Consequently, they are under the jurisdiction of the states. There is not only no reason why every effort should not be made to obtain uniformity of legislation along these lines in the various states but there is every reason why an enlightened and intelligent civilization should demand uniform legislation on these subjects based on rational investigation and sound economic principles. From the standpoint of our profession it may be said that uniformity in laws regulating the practice of medicine is the most effective means of bringing about reciprocity. For this reason it is to be hoped that should such a convention materialize the governors of the various states will see fit to appoint as one of the three delegates from each state a progressive member of the medical profession. There is no state that can take the lead in such a matter with a better grace or more authority than the Empire State. It is to be hoped that this bill will lead to definite and tangible results.

The Weak Points in Organization

Dr. W. P. Wherry, Fort Wayne, Ind., writes: "The medical profession in the United States seems now to be very well organized. Physicians are grouped in county, district, state and national associations, the chief difference between these being that a wider and wider circle is necessary to circumscribe them in the order named. Practically the work of every group is identical. Papers are read and discussed and much useful postgraduate instruction is afforded. To a small extent, the social or fraternal feature is cultivated, but the highly important subject of economics—the legislative business interests especially—is neglected or attended to in such a perfunctory manner that injury in stead of benefit results. We do not find the collateral profession of lawyers making a similar mistake.

The weak point of the organization of medicine is the state society. There is no good reason why it should be a mere *fac simile* of the county society enlarged. Under the constitution of the United States the whole legislative regulation of the profession belongs to the several states. This is a reason why the state society in its public sessions should devote most of its time to the business interests of its members and reserve the time devoted to scientific matters as these are fully taken care of in the county, district and national associations. If the state society would include in its

subjects of the sections into which the American Medical Association's work is divided, the rest of the time might be devoted to medical economics. The laws that concern the profession are generally promoted by a small number of persons, and the practitioners affected by them have no opportunity to express any opinion on legislative projects that may be injurious. After all, the bulk of the medical societies consists of general practitioners, with whose business interests the specialists who are prominent at the meetings have no sympathy. Contract work, insurance work, public services and the collection of fees for attendance on private patients are matters deserving much attention at the meetings of the state societies. Instead of being relegated to committees, these things should form a main part of the work of the general sessions. If this change were adopted very few practitioners in a state would be found outside of the state association of the school to which they belong."

Public Meetings by County Societies

The advantages to be gained by county societies holding occasional public meetings is interestingly discussed by Dr J. M. Allen, of Liberty, Mo., in a recent number of the *Journal of the Missouri State Medical Association*. As a means of securing favorable legislation and appropriations for sanitary purposes such meetings would prove invaluable, and Dr Allen recommends that at least one such meeting should be held annually. He also emphasizes the importance of the education of public school teachers on matters of sanitation and hygiene and suggests the appointment, in each county, of a member of the county society to deliver to the school teachers, at their county institutes, addresses on public school hygiene and other matters along medical lines. This last suggestion is practical as well as valuable and there is no reason why it can not be carried out in every county in which medical organization exists. Every teachers' institute and organization would gladly welcome such an arrangement. The influence for good which would thus be exerted both on the teachers and their pupils can not be over estimated.

Reasonable Fees for Insurance Examination

The position of the profession on the life insurance examination question was recently the subject of editorial comment in the *Interview*, a paper published in New York. The writer says, in part:

"Physicians have begun war on the old line life insurance companies, resisting the proposed cut of medical examination fees from \$5 to \$3. In view of the extremely high cost of even moderate living nowadays, and in view of the fact that doctors, who are properly fitted for their profession, have had to spend much cash and long years of laborious study, we fully believe that they are perfectly justified in demanding a reasonable fee for making thorough examination of applicants for life insurance, and we do not believe that \$5, on an average, is any too much compensation for a skilled physician for the time required to make a trustworthy examination."

What Is Contract Practice?

A correspondent writes: "What is the meaning of the words 'contract practice' as used in paragraph 4 of 'Why You Should Join a County Medical Society'?" The paragraph referred to reads: "Because it makes possible among physicians better business conditions and methods, including fee bills, defense and avoidance of contract practice, etc." As these matters lie within the jurisdiction of the county society, the construction placed on the terms used therein also lies within the same province. Each county society has a right to decide for itself what constitutes contract practice. In a country as large as ours, with interests so varied and local conditions so diversified, a definition, at once inclusive and exclusive, is difficult, if not impossible. The objectionable features of contract practice are the payment of a definite amount of compensation for an indefinite amount of service; the payment, for services rendered during the life of the contract of an amount far below that which would be received for the same services if they were paid for in detail; and the competition engendered between physicians which leads them to underbid each other, thus causing dissensions, etc.

Medical Societies in St. Louis Cooperate

Representatives of the medical societies of St. Louis have organized "the Joint Medical Council" for the purpose of improving the management of the city hospitals and dispensaries. At present, the health commissioner and the superintendents of the various public benevolent institutions in the city are appointed by the mayor. The council has recommended the organization of a board of trustees, to be chosen at municipal elections and to consist of six members, beside the mayor as an *ex officio* member, this board to have control of the city hospitals and associated dispensaries, as well as of all of the public charitable institutions now in the city or that may be established in the future. It further recommends that this board of trustees appoint, from the physicians of the city of St. Louis, a representative medical staff, which shall have charge of the medical and surgical work in the public institutions.

The Council is composed of 21 representatives from the following societies: St. Louis Medical Society, Medical Society of City Hospital Alumni, St. Louis Homeopathic Medical Society, St. Louis Hahnemannian Club, St. Louis Children's Hospital Alumni Association, St. Louis Eclectic Medical Society, St. Louis Dental Society, St. Louis Surgical Society, St. Louis Surgical Club, St. Louis Obstetrical and Gynecological Society, and the *Veren Deutscher Aerzte*.

Legislation Notes

Dr G. N. Streeter, Brooklyn, N. Y., writes regarding the passage of the medical practice act in Delaware:

"Why can not such legislation be brought about in every state, and thus banish the Christian science healers, osteopaths and others who have not complied with the arduous and expensive requirements exacted of members of the medical profession? Why should we be discriminated against in this manner by the different states? Will the apathy of doctors continue until our profession is thrown from the place to which it is entitled in the community by those who play on the delusions and credulity of the gullible public? Why can not the American Medical Association, at its next meeting, appropriate money and appoint committees to bring this matter before the legislatures of the different states and also discuss the matter in each publication of *THE JOURNAL*?"

Dr L. R. Murkley, Bellingham, Wash., writes regarding the work of the legislature in that state:

"Our state legislature has just adjourned and, as usual, the wants of the profession were not given as much consideration as we had hoped for. The coroners' bill was defeated. The watershed bill was also killed, this was a meritorious measure designed to give better control of the water supply. The tuberculosis bill and all medical practice bills were also killed. We succeeded in getting a fairly good pure milk and pure food bill passed, also a bill relating to vital statistics. It seems strange that we have to work so hard to get bills that are solely for the public good adopted by the state legislature. At every turn 'private interests' are butting in and, as they have money to spend, they usually win, until public interest is sufficiently aroused to compel attention."

Dr B. D. Black, secretary of the New Mexico Board of Health, reports the passage by the legislature of house bill No. 53, which regulates the practice of medicine and provides for a medical examining board. Dr Black says: "It is a compromise bill and is not what we asked for or expected but it is such a material improvement over our old law that we feel that we can congratulate ourselves."

Pottawatomie County (Okla.) Medical Society reports a membership for 1906 of 32. During the year it held 57 meetings, with an average attendance of 15. The society is now meeting every Saturday night. If such work can be done in one of our new western states, what might not be possible in the older and more settled portions of the country, where it is much easier for physicians to attend and to support a medical society?

DISEASES OF THE NERVOUS SYSTEM Resulting from Accident and Injury. By P. Bailey, A. M., M. D. Clinical Lecturer in Neurology, Columbia University, New York City, etc. Cloth. Pp 327. Price, \$5.00. New York: D. Appleton & Co. 1906.

The tendency to see a causal relationship between two events merely because one follows the other in point of time seems to be deeply rooted in the human mind. This applies not only to the ordinary phenomena of Nature, but also particularly to matters relating to medicine. Were such faulty deductions limited to the laity the profession might easily overlook it, at least so far as medical matters are concerned, but unfortunately the same weakness is but too prevalent among physicians. In no particular is this so manifest as it is in the tendency shown by some to attribute to some antecedent injury all of the subsequent ills which may befall an individual. Owing to the great lack of knowledge, on the part of many physicians, of the anatomy, physiology and pathology of the nervous system, the relationship which exists between injury and nervous diseases, is but little understood. The appearance of this work, therefore, by one of such wide experience, is very timely.

The volume is divided into three parts. 1, On "Organic Effects of Injury to the Nervous System," 2, on "Functional Effects of Injury," and 3, on "Medicolegal Considerations." There is an introductory chapter on the general methods of examination for the actual injury, which is good and should be carefully studied. Then follow chapters on actual injuries to the various parts of the nervous system, particular attention being given to the prognosis of such injuries. Almost half of the volume is devoted to the "Functional Effects of Injuries," which indicates how frequent and important is this class of disorders. In this connection we make the following quotation which is, alas, but too true: "The influence of suggestion by physicians is frequently traceable in the causation of traumatic neurasthenia and of traumatic hysteria. In many cases it seems as though these disorders owe their appearance, in a large part at least, to the fact that the patients have been told by physicians that they may some day have trouble with the spinal cord as a result of the accident. The examples of the bad effects of such ill advised statements are numerous."

The chapters on "Personal Injury Claims," "Expert Witness," "Malingering," "Substitution of Origin," "Simulation," etc., are extremely interesting and instructive. The great prevalence of personal injury suits of all kinds against corporations and individuals the tendency toward industrial insurance and the enactment of more rigid indemnity laws, make it incumbent on every physician to become more thoroughly informed on the subject of injuries and their results. Therefore, this work can be most heartily recommended.

A TREATISE ON SURGERY By G. R. Fowler, M.D. Examiner in Surgery, Board of Medical Examiners of the Regents of the University of the State of New York, etc. 888 Illustrations and 4 Colored Plates all original. Cloth. Pp 722. Price \$15.00 net. Philadelphia: W. B. Saunders Co. 1906.

A glance at the table of contents of this book shows that an ambitious effort has been made to cover the entire field of surgery, the design being encyclopedic and the work in its entirety constituting a memorial to the ability, skill and industry of the lamented Fowler, whose individuality is clearly stamped on its pages. In a work of such broad scope, under taken by a single author, it is to be expected that some shortcomings will be found and it is to be regretted that a second edition will not have the benefit of revision by its distinguished author. More than one half (428 pages) of the first volume is devoted to the principles of surgery and minor surgery. The descriptions of disease processes are, on the whole, fairly accurate but some noteworthy contradictions are met in this connection. The book opens with the subject of inflammation which, from the viewpoint of the surgeon he very properly defines as "that series of changes in the tissues which take place as the result of injury plus infection." Later we find aseptic wound healing described as "regenerative inflammation," a manifest misnomer according to the preceding definition. Again, the statement "Fever is an increased

tissue metamorphosis, the essential result of pathogenic bacteria. This influence may be exerted directly by the presence of the micro organisms themselves or indirectly by the products of decomposition and the presence of ptomaines" will hardly meet the requirements of modern surgical pathology and is flatly opposed on the next page by the remarks on aseptic wound fever and experimental fever resulting from intravenous infusion of salt and other solutions. The section on laboratory aids in surgical diagnosis and prognosis is clear, full and practical as are also those on anesthesia and bandaging. We note in the section devoted to operative technique, otherwise well written and of direct practical value that the circular method of amputation is given to transfexion over the incision. The old fashioned method of draining through the suture line is recommended instead of the modern plan of establishing drainage through a puncture in the most dependent portion of the stump. The remaining portion of the two bulky volumes, devoted to regional surgery, is well arranged for reference, beautifully illustrated thoroughly indexed and though dealing but briefly with many subjects is in general a reliable guide to the modern practice of surgery.

MANUAL OF PRESCRIPTION WRITING with a Full Explanation of the Methods of Correctly Writing Prescriptions. By Matthew D. Mann, A. M., M. D. Professor of Obstetrics and Gynecology in the Medical Department of the University of Buffalo. Revised by F. Cox, M. D. Sixth Edition. Revised and Enlarged. Cloth. Pp 232. Price \$1.00. New York and London: G. I. Putnam's Sons. 1907.

This little manual covers a range of subjects important to the practical physician, and it aims to supplement current medical teaching in some of the details in which it is admittedly deficient. The ordinary course is followed, the parts of a prescription, the weights and measures commonly used, the language and abbreviations and grammatical construction being described with some detail. The different classes of preparations, with examples of prescriptions for powders, pills mixtures liniments, and the various forms of medicine intended for external use are then described. A discussion of doses the metric system the combination of medicines and incompatibilities completes the work. The utility of the one who appreciates the need of elegance and accuracy in any important matter of prescription writing. The book has been revised to accord with the latest revision of the Pharmacopeia, but we regret to note that this revision has overlooked some verbal errors which are unfortunate in a work intended to teach verbal and grammatical accuracy. Pepsine for pepsin and glycerine for glycerini occur as well as oleum theobromae for oleum theobromatis. These errors, which are of importance in a work like that under consideration will doubtless be corrected in the next edition.

TEXT BOOK OF OPHTHALMIC OPERATIONS By Harold Grimesdale, M. D., F. R. C. S. Ophthalmic Surgeon to St. George's Hospital and F. Moore Brewerton, F. R. C. S. Ophthalmic Surgeon to the Metropolitan Hospital. 10th Edition. Pp 340. Price \$5.00 net. Chicago: W. T. Keener & Co. 1907.

This is a compilation of eye operative procedures by two well known English ophthalmologists. In addition to the description of the operations an introduction is given covering the necessary anatomy physiology and surgical anatomy of the parts to be operated on. The literature has been fully reviewed and a condensed account of the various operations, with the name of the originator, is given. References to the original point they are clear and practical, which is the main requirement. The illustrations are all schematic and done in black and white. While they might be improved from an artistic standpoint, they are clear and practical, which is the main requirement.

NATIONAL ASSOCIATION FOR THE STUDY AND PREVENTION OF TUBERCULOSIS Transactions of the Second Annual Meeting. Washington, D. C., May 16 to 18, 1906. Paper. Pp 634. Lancaster: The New Free Printing Co.

The forty-one papers included in this volume many of which have been published elsewhere discuss a large variety of topics relating to tuberculosis and furnish a body of reading on questions of great importance to every physician. Abstracts of many of the report of the meeting in *THE* 1906 Pp 1720 and 1907.

AN INTRODUCTION TO PHYSIOLOGY By William Townsend Porter M.D., Associate Professor of Physiology in the Harvard Medical School Cloth Pp 587 Price \$2.50 Philadelphia J B Lippincott Company, 1906

This is a collection of fundamental and accessory experiments in several fields printed in abbreviated form for temporary use. Dr. Porter evidently recognizes that the student is best taught by observation, as he bases his studies on experimental results, the student being required to perform each experiment. This makes the study of physiology practical and far more profitable than when taken up didactically. The subject is presented in an excellent manner.

OBSTETRICS FOR NURSES By J. B. DeLee, A.M. M.D., Professor of Obstetrics Northwestern University Medical School etc. Second edition thoroughly revised and enlarged. Cloth Pp 510 Price \$2.50 net. Philadelphia W B Saunders Company, 1906

Though this book is intended primarily for nurses, it will be of value to medical students and to recent graduates, as the duties of a nurse often devolve on physicians, especially during the first few years of practice. The technique in normal and abnormal cases is fully described and illustrated. The illustrations, many of which are from photographs, are excellent. The book contains much valuable information regarding the so-called minor points, mention of which is generally omitted from the larger works.

MEDICAL SOCIETY OF THE MISSOURI VALLEY

The President, Dr. O. Beverly Campbell, St. Joseph, Mo., in the Chair

Nephrolithiasis Urica

Dr. A. C. Croftan, Chicago, presented a very full discussion of the prevention and treatment of this condition. He said that surgery can do no more than remove the calculi or establish drainage in infected cases, but it can not, in any way, influence the factors that determine the formation of uric acid calculi, that is, surgery can not cure nephrolithiasis. The treatment should be directed toward preventing the deposit of urates in the lower urinary passages, and with this end in view there must be considered the dilution of the urine, the total amount of uric acid and sodium chlorid in the urine, and the reaction of the urine. The patient should drink freely of water, not necessarily mineral waters, because it is the water and not the mineral it may contain that is of value. The liquid intake should exceed by far the original liquid output in the urine.

The diet should take into consideration the nuclein content of the food, and nuclein containing organs should be eliminated from the diet. Dr. Croftan said that albumin *per se* is in no way a source of uric acid. It is very important not to underfeed the patient. Dr. Croftan advised the administration of alkalis, particularly of calcium carbonate, but advises caution in its administration in infected cases.

Surgery of the Thyroid

Dr. Alex. Hugh Ferguson, Chicago, in the oration on surgery, reviewed the indications for surgical intervention in diseases of the thyroid gland, the diagnosis of enlargements of the gland, and the methods of procedure for removal of the gland which he has found to be most valuable. He said that, generally stated, surgical intervention is not called for until other measures have been tried and failed. A study of 300 cases of thyroidectomy showed that in 77 per cent dyspnea was the principal indication for operation, deformity in 24 per cent, dysphagia in 8 per cent, tracheal stenosis and discomfort in about 3 per cent. He has operated on 58 patients. In 44 cases of simple or cystic goiter there was no mortality. In 12 cases of exophthalmic goiter the mortality was 25 per cent. The causes of death were thyroidism in 2 cases and collapse of the trachea in one case. Four of the patients were in very poor condition and two of these died.

Gastroptosis

Dr. Robert T. Sloan, Kansas City, Mo., advocated general hygienic measures, diet, mechanical support and rest in bed, the foot of the bed being elevated slightly, in the treatment of gastroptosis.

Treatment of Morphin Habit.

Dr. W. F. Waugh, Chicago, stated that, inasmuch as toxin retention is the disease, elimination is the remedy. With drawal symptoms, he said, are an evidence of autotoxemia. By eliminating the toxins as fast as they are poured into the system there will be no withdrawal symptoms. He has treated a considerable number in this manner with great success.

Non-operative Treatment of Gastric Diseases

Dr. F. B. Turck, Chicago, said that cases which manifest disturbance of function, but where no stenosis is found, do not demand surgical treatment, but rather physiologic methods of treatment, that is, dietetic, physical and mechanical. Operative treatment is indicated when there is obstruction of the stomach outlet, as in benign superficial stenosis or early malignant growth, when the diagnosis is uncertain and characterized by progressive loss of weight and when all symptomatic treatment fails.

Pelvic Abscess

Dr. W. T. Elam, St. Joseph, Mo., advocated hysterectomy by the two stage method in case of multiple abscesses of the uterus, vaginal drainage in walled off abscesses, salpingectomy or oophorectomy, when demanded, as secondary measures. In cases of chronic pyosalpinx the abdominal route is preferred.

Hernia.

Dr. D. C. Hilton, Lincoln, Neb., classifies hernia as follows: (1) Hernioida protrusa and (2) hernia vera. Among the first are cases of protrusion invested by the mucocutaneous membranes of the body through an orifice of the mucous or cutaneous surface.

The second class, hernia vera, comprises the congenital and acquired hernia. This classification is based on the conception that the body is a tube, the continuous covering of which is epithelium, which spreads over the general inner and outer surfaces of the tube, and also into all diverticula and recesses.

Experience with Morphin Hyoscin Compound

Dr. F. E. Walker, Hot Springs, S. D., reported 75 cases in which he made use of this compound with most excellent results. No untoward symptoms were observed and no evil effects were noted as the results of large dosage.

Dangers from Tuberculous Milch Cows

DR. S. R. TOWNE, Omaha, stated that evidence is accumulating supporting the theory that infection of the lung occurs not by inhalation, but by the ingestion of bacilli, and that there exists an intercommunicability of all types of tuberculosis, the bovine being the most active. He emphasized the greater susceptibility to tuberculosis of the child, and pointed out that milk must be reckoned with as a probable source of infection in tuberculosis. He said that any system of prophylaxis which ignores the tuberculous milch cow must be considered incomplete.

Treatment of Exophthalmic Goiter with Electricity

DR. R. D. MASON, Omaha, reported one case in which the main feature of treatment consisted of the introduction into the thyroid of iodine by cataphoresis. The patient, aged 45, had manifested symptoms for two years. Treatment was instituted six months after the onset of the disease and was given twice a week for six weeks. Strychnin was the only agent given internally. Improvement was marked and steady from the beginning of the treatment. The circumference of the neck finally was two inches less than when the patient was first seen, although the pulse rate was still about 100, and the pulse was quite irregular. The tremor was much improved, there was no pain, the eyes were normal, and in somnia, from which the patient had suffered severely, was relieved.

Other Papers Read

The following papers were also read:

"Gall Bladder Disease" by Dr. A. L. Wright, Carroll Iowa
'Specialism' by Dr. P. I. Leonard, St. Joseph, Mo.
"Some Views on Appendicitis" by Dr. C. O. Thlenhaus, Milwaukee
"Pulsating Exophthalmos Treated by Excision of the Superior Ophthalmic Vein," by Dr. H. Gifford, Omaha
"Renal Calculi," by Dr. B. A. McDermott, Omaha
'Vesicovaginal Fistula,' by Dr. F. A. Long
Madison, Neb.
and "Anterior Suspension of the Uterus," by Dr. F. B. Dorsey, Keokuk, Iowa

The annual meeting will be held in Council Bluffs, Iowa, Sept. 5, 1907.

OBSTETRICAL SOCIETY OF PHILADELPHIA.

Regular Meeting, held Feb. 7, 1907

The President, DR. WILMER KRUSEN, in the Chair

Chorea During Pregnancy

DR. COLLIN FOULKROD reported a case of a patient in whom chorea occurred in the course of five successive pregnancies, possibly causing the death of three or four of the fetuses. By careful watching he succeeded in carrying the woman to term and delivering her of a living child. Bromid and chloral were administered.

Diagnosis of Early Pregnancy

DR. ELLICE McDONALD examined 100 cases at various weeks of pregnancy. The duration of the pregnancy was calculated from the date of the last menstruation. The pelvic signs were the only ones closely studied. Jacquemien's sign of the violet hue of the vagina was found to be of the most value after the eighth week. It was first noticed at a spot just below the urethra. Blush of the cervix was noted in much the same percentage of cases as Jacquemien's sign. It was also noted that in the early stages of pregnancy there is a marked difference in the ease with which the body of the uterus can be moved on the cervix and the cervix on the fundus. This was usually best noted about the fifth week and is usually so marked that the body and the cervix may be doubled on themselves and brought together, the empty bladder and vaginal walls alone separating them. This sign was best obtained by placing the palmar tips of the vaginal fingers posteriorly and below the end of the cervix and the fingers of the abdominal hand on the top of the fundus. The bladder must be empty and there must be no contraction of the uterus. The sign is easily obtained after slight practice. It may be obtained before there is thinning of the lower segment but is caused by the same conditions which produce Hegar's sign.

DR. BARTON COOKE HIRST spoke of the possibility of gross error of diagnosis in early pregnancy and of the necessity of methodical examination of patients. The sign to which atten-

tion had been called in Dr. McDonald's paper he has always grouped with Hegar's sign, making no distinction between the softening of the lower segment and the thinning. Among the signs of early pregnancy on which he depends, the softening of the cervix holds an important place. The eccentric hypertrophy of the cervix he also regards as an important sign. Without this he does not think pregnancy is possible, and by its absence it is often impossible to say that pregnancy could not exist in a certain case. If, on the contrary, the cervix is much broader and softer than normal, pregnancy is at least probable. The change of color in the genital tract he regards as a valuable symptom when obtainable. It, however, is lacking in a considerable percentage of the early cases, the very cases in which the diagnosis is most difficult and most desirable. One fact about the change of color which is seldom mentioned is that as pregnancy advances the blue or purple discoloration of the genital canal is sometimes absent, but he has never seen a case in which, if this blue discoloration is absent, there is not a transformation of the pink of the mucous membrane of the introitus and vestibule into a bright scarlet.

DR. EDWARD P. DAVIS said that in an examination and diagnosis of early pregnancy a systematic procedure is of the utmost importance. The head, face and neck of the patient should be investigated to determine the enlargement of the thyroid, alterations in the pupils, abnormalities in the color of the face and the presence or absence of abnormalities in the nose, throat and mouth. In some normal pregnancies the thyroid is said to be slightly enlarged, while in pseudocyesis the thyroid is often considerably diseased. The action of the heart is readily excited during pregnancy and hemic murmurs are often present in the early months. One of the most significant symptoms of early pregnancy in gouty and neurotic women, he said, is a generally irritable condition of the mucous membrane of the nose. In one such case the condition at once disappeared after abortion. Dr. Davis said that he has been accustomed to search for softening in the lower uterine segment and to consider this as strongly suspicious of pregnancy. In examinations this phenomenon is usually associated with enlargement of the uterine body and the two are taken together as practically constituting Hegar's sign. Disturbances in metabolism are present in early pregnancy. Color signs in the genital canal he regards as suggestive rather than decisive. When the examination of the uterus gives several signs significant of pregnancy and the general examination of the patient coincides, the patient is probably pregnant, but a positive assertion should be withheld until positive evidence of fetal life is obtained.

DR. RICHARD C. NORRIS believes that the positive diagnosis of early pregnancy will always be a very difficult matter in spite of the most advanced refinements in diagnostic means. One of the most practical points is to examine the patient at intervals and repeatedly before coming to any conclusion in doubtful cases. Since women differ greatly in anatomic peculiarities such for example as the flexibility or eccentric enlargement of the cervix it is necessary to reserve even a presumptive diagnosis until the patient is seen on more than one occasion. He confesses that he has yet to make an early positive diagnosis by means of any of the early diagnostic signs and has had to wait until time and other signs made the diagnosis positive.

He has studied many cases of early pregnancy for Hegar's and Braxton Hicks' signs and believes that the personal equation of the examiner is an important factor and that a part which may feel soft one day may not at the next visit. He feels that Dr. McDonald has done some careful work in exploiting flexibility or thinning of the lower uterine segment as an early sign of pregnancy. Personally he has not felt justified to conclude that there is thinning of the lower uterine segment without recto vaginal examination. The sign which has helped him most is the change in the shape of the uterus presenting what is termed a jug-shaped uterus.

DR. CHARLES P. NORRIS feels that at or before the tenth week the clinical signs mentioned seldom assist in a definite diagnosis. The "jug sign" of pregnancy has been most helpful to him in the early diagnosis of pregnancy. In his experience Hegar's sign is of little value before the twelfth week.

DR. GEORGE M. BOYD emphasized the necessity of repeated examinations. He has found Hegar's sign of value and also the change in the shape of the upper segment of the uterus. He referred to two cases which had come to his notice in which the diagnosis of uterine and ectopic gestations had been confounded.

Pubiotomy

An abstract of Dr. Richard C. Norris' paper appears in THE JOURNAL, April 13, page 1298.

DISCUSSION

DR. CHARLES P. NOBLE has not done this operation and personally sees no advantage in sawing through bone to cutting through the symphysis. In Heidelberg he learned of a case of fatal hemorrhage after operation.

DR. BARTON COOKE HIRST has done two pubiotomies during the last two weeks. In the first case he had occasion for much enthusiasm, but the second gave him much trouble and anxiety. The first was a patient whom he had delivered five years before by Cesarean section. After etherization the cervix was dilated with Bossi dilators, a Pomeroy bag inserted and the patient laid aside, and at the end of an hour and twenty minutes she was again anesthetized and the operation done, resulting in the easy extraction of the child and the subsequent well being of both mother and child.

In forty eight hours later he had an illustration of almost all the disadvantages of pubiotomy in a woman in labor for thirty six hours. The first disadvantage encountered was from the woman's obesity. There was a rachitic pelvis and the child was much over size, and the operation was attended with various other difficulties. Four days after delivery the woman developed symptoms of infection. The patient recovered. Dr. Hirst believes that for the general practitioner who must operate in insuperably obstructed labor Cesarean section is the operation of choice.

Fibroma of Uterus

DR. GEORGE ERETY SHOEMAKER said that no arbitrary limit can be placed in the reduction of hemoglobin, beyond which hysterectomy is unjustifiable if demanded to save life. A woman was shown, removed by supravaginal hysterectomy from a single woman aged 35, whose hemorrhage had reduced her hemoglobin to 25 per cent. Her mucous membranes were almost white. She had shortness of breath and tinnitus and was subject to asthmatic attacks. The tumor, multinodular, interstitial, weighing about three and a half pounds, was hard and irregular, invading every portion of the uterus. Intravenous salt solution injected during operation, great care in conserving body temperature and attention to detail brought about a normal convalescence, the highest pulse being 98, and that immediately after operation.

Another uterus was shown with a large intramural degenerating fibroma. The patient was aged only 29, but had been greatly debilitated both by hemorrhage and the absorption of toxins from the tumor. The hemoglobin was 62 and was, therefore, not the real index of the amount of systemic change. The tumor was grayish white, with areas shading to dark gray. Macroscopically it resembled sarcoma, but the microscopic report was fibroma.

FIRST COUNCILOR MEDICAL SOCIETY OF MICHIGAN

Third Annual Meeting, held March 28, 1907

DR. J. H. CARSTENS, Detroit, in the Chair

The third annual meeting of the First Councilor Medical Society, Michigan, comprising the county societies of Lenawee, Macomb, Munroe, Oakland, Washtenaw and Wayne, was held March 28, 1907, at the Hotel Cadillac, Detroit. About 125 sat down at the banquet. The toastmaster was Dr. David Inglis, Detroit. Dr. A. W. Chase, Adrian, replied to the toast "The General Practitioner," Dr. J. D. Riker, Pontiac, replied to "The Doctor's Price," Dr. A. M. Barret, Ann Arbor, to "The Relation of the Psychopathic Hospital to the General Practitioner," and Dr. V. C. Vaughan, Detroit, to "The Specialist."

The following papers were read at the afternoon session

The Advantage of Laparotomy Over Tapping in Ascites

DR. GEORGE DOCK, Ann Arbor, urged incision, instead of paracentesis, in all ascitic cases in which the diagnosis is uncertain, in order to avoid the slight risk involved in paracentesis, and to provide the best opportunity for making a certain diagnosis and applying surgical measures, if indicated, immediately.

DISCUSSION

DR. T. A. MCGRAW, Detroit, said that he has incised many ascitic patients who were in very dangerous condition, without shock or other bad result. An advantage of incision over puncture is that incision can be followed by drainage, if needed, as in tuberculous peritonitis.

DR. C. S. OAKMAN, Detroit, said that ascites usually indicates a serious cause. If cardiac or renal, the cause can usually be found without exploration. If hepatic, diagnosis without operation is more difficult. If inflammatory, tuberculous or neoplastic, incision is needed not only for diagnosis, but the early surgical therapy that incision makes possible is of great value.

DR. J. H. CARSTENS, Detroit, said that he has not done a paracentesis of the abdomen for twenty years, because he regards it as dangerous and nearly always less advantageous than incision. But paracentesis may occasionally be advisable in order to facilitate palpation, and by this means to learn where to make the exploratory incision, above or below the umbilicus.

Importance of Complete Extirpation in Tonsil Operation.

DR. E. T. MORDEN, Adrian, said that after partial removal of the tonsils there is better opportunity for infection than before, although the obstructive symptoms may be relieved. So called regrowth means incomplete removal.

DISCUSSION

DR. D. M. CAMPBELL, Detroit, said that he is in the habit of leaving some of the tonsil in order that the part left might exercise the probably beneficial function of the tonsils. It is impossible to extirpate the tonsil with a tonsillotome, a punch or scissors must be used afterward for complete removal.

DR. J. V. WHITE, Detroit, said that if the condition is inflammatory and recurrent, and the lacunæ extend deep, total enucleation is indicated.

DR. A. P. OHLMACHER, Detroit, said that hypertrophy of the tonsil might indicate the status lymphaticus, on account of which the anesthetic and shock of the tonsil operation might prove serious.

DR. WILLIS S. ANDERSON, Detroit, said that the reasons for removal of the tonsils are either mechanical or absorptive. If mechanical, partial removal may be sufficient, if, however, removal of the tonsil is indicated to prevent absorption, the normal function of the tonsil is lost, and the tonsil should be removed completely. The atrophy of the faucial pillars, he said, is due to needless damage done the pillars in the enucleation, and not to complete removal of the tonsil. The tonsil should be dissected off the pillars accurately. In children partial removal may be all that is needed or safely possible. The remote possibility of the status lymphaticus should not prevent the operation. A bent probe is a useful means of investigating crypts and pockets, and crypts and pockets in the tonsil are of more importance than simple hypertrophy.

DR. EMIL AMBERG, Detroit, said that the normal tonsil has no needed function.

DR. R. S. ROWLAND, Detroit, has observed in several children more symptoms from the tonsil after the tonsil operation than before it.

Empyema.

DR. R. Y. FERGUSON, Pontiac, emphasized the importance of early diagnosis by the aspirating needle, especially in children, and the need for prompt drainage by rib resection.

DISCUSSION

DR. A. P. OHLMACHER, Detroit, reported two cases of empyema that had been strikingly benefited by artificial autogenous vaccination.

DR. KENNETH GUNSOLUS, Detroit, believes that it is not always necessary to resect a rib in children. In adults, how every rib resection seems always wise.

The following cases were exhibited "Sciatica Due to Sprain of Sacrospinous Joint," by Dr W E Blodgett, Detroit, "Case of Rhinolith," by Dr J W White, Detroit, "Exophthalmic Goiter," by Dr C M Hagen, Detroit Papers were read on "Opsonins and Bacterial Vaccines," by Drs E C Miller and E M Houghton, Detroit.

Therapeutics

[It is the aim of this department to aid the general practitioner by giving practical prescriptions and methods of treatment for the diseases seen especially in every day practice Contributions will be welcomed from our readers.]

ONITMENTS

By W A. Jolley, M.D

BOULDER, COLO

FATS AND OILS

The customary distinction between fat and oil is that one is a solid and the other is a liquid. They are abundant in Nature and easily obtained. Their use in medicine is accompanied by the usual fantasies which tradition favors old remedies There is a fascination which the names goose grease, skunk oil, rat tlesnake oil, etc., convey that will not be displaced in the minds of the laity or the medical profession by hard scientific facts We find their principal use in salves which were applied on any and all occasions, the most obnoxious smelling and abhorrent mixtures being credited with the greatest healing powers

Antiseptic surgery did not cause a diminution in their use, but created a new field as vehicle for the multitudinous antiseptic agents Advance in the knowledge of organic chemistry has given us a better understanding of individual members of the fats, but has caused confusion by adding so many new ones to the already large list

MINERAL FATS

The elegant mineral fats now on the market have nearly supplanted the vegetable and animal fats which were our main reliance, this should not be the case, for each has its use Crude petroleum is a complex mixture, which gives a series of products, rhigolene, gasoline, benzine, kerosene, and a solid residuum from which we get vaselin (petrolatum), paraffin lubricating oils, and many other substances

The Pharmacopœia gives Petrolatum Liquidum, Petrolatum Album, Petrolatum and Paraffin The only practical difference is their melting points Ointments of any degree of solidity can be made by combining the proper amounts of each Interesting manufacturing chemists have improved on these U S P standards and furnished splendid preparations of the mineral oils from the liquid ones to be used in atomizers to the hard waxes, giving each a trade name

The mineral fats are not subject to any chemical reaction at the temperature ointments are used they are not oxidized do not form irritating salts nor break up into other compounds, and should be used as vehicles for active principles to produce local antiseptic anesthetic irritative and protective action They are not absorbed by the body and should not be used when systemic effect is desired through external applications

The fact that they are not subject to chemical change renders them specially adapted to all cosmetic purposes for the animal and vegetable fats will often become rancid and offensive to the sense of smell and irritating to the surface to which they are applied Cold Cream (Unguentum Aquæ Rosæ) is an elegant pharmaceutical mixture and should be used more than it

is, but it will occasionally become rancid. A similar appearing mixture which will not deteriorate with age can be made by substituting Petrolatum Liquidum for almond oil. The presence of borax in cold cream causes it to become discolored when certain chemicals are added to it. This would not happen with mineral fats, for no antiseptic is needed to keep them from becoming rancid. If Unguentum Aquæ Rosæ is prescribed the ointment should be made as given in the U S P, unless there is an understanding between the druggist and physician.

VEGETABLE AND ANIMAL FATS

Most of the vegetable and animal fats belong to the chemical class known as the fatty acids. Those of practical use are palmitic, stearic and oleic acids. They do not exist as acids in Nature, but as glycerids, that is in chemical combination with glycerin. They are not found separate, but always together in varying proportions, in vegetable fats, oleic acid predominates, causing them to be liquids, in animal fats, the excess of either stearic or palmitic acid causes them to be solid.

Some slight chemical reaction in the growing plant causes a small portion of the fat to assume a certain definite composition, which gives each oil a distinctive feature. For example, linseed oil is characterized by linoleic acid, an oxidation product of oleic acid, castor oil by ricinoleic acid, etc. These various oils and fats also contain bodies which give each a distinctive odor, while they may be nearly alike chemically. They form salts with alkalis, which we call soaps, sodium salts are generally solid, and potash salts or soaps are soft.

The higher members of this class, the ones we are discussing, are insoluble, but readily break down into lower members of the same class, which are soluble butyric acid and others, which fact enables us to separate the two by washing with water.

Fats exist in Nature in the form of minute globules invested by a proteid membrane, in large masses in the animal and in certain tissues in the vegetable. The animal tissues are cut into fragments, to facilitate the release of the fat from its investing sheath, are liquefied by the application of heat, and removed by straining and pressure. In removing the vegetable oils pressure alone is used to remove a part of the oil, the highest grade, heat is then applied, followed by pressure, which produces an oil of lower grade. If the membrane is not entirely removed it decomposes readily and causes the fat to become rancid. This is shown by the rapid decomposition of butter when the casein has not been entirely removed. This decomposition is a chemical change resulting in the formation of other compounds offensive in odor and irritating to the skin or mucous membrane. It is also facilitated by many organic drugs, so we often find salves which are intended to be bland applications turn into very irritating applications. It is stated that the organic preparations which liberate oxygen should always be combined with the mineral fats for this reason. The common oils and fats are Linseed, olive, almond and cottonseed oils, suet, tallow, lard and others which are likewise suitable for pharmaceutical use, but commercially impracticable.

Linseed Oil—Linseed Oil (Oleum Lini) is a mixture of from 10 to 15 per cent of palmitin and stearin, and from 85 to 90 per cent of the glycerids of oleic and linoleic acids. The last mentioned acid is an oxidation product of oleic acid and gives this oil its distinctive features. It is called a drying oil for the oxidation, having begun, continues rapidly when exposed to air, and forms a hard resinous mass, if in bulk, or a hard film when spread over a surface. This is the reason for its use in painting. If the oil be finely subdivided, as on old rags, the oxidation takes place so rapidly that it bursts into flames. This is the cause of so many fires of spontaneous combustion, and should be considered when large quantities of Carron Oil (Linimentum Calcis) are applied on gauze to burns. The process of drying or hardening is facilitated by boiling the oil with oxidizing substances, such as lead acetate, red lead, litharge, manganese dioxide, manganese borate and others. Boiled oil is then very different from the raw oil, yet few druggists know the distinctive features of the two.

Other oils which belong to this class are candlenut oil, corn

oil, grapeseed oil, hempseed oil, nigerseed oil, pumpkinseed oil, sunflower oil, walnut oil and wood oil. These oils are not suitable for use in ointments, except when a hard base is required, or for immediate use.

Olive Oil and Almond Oil—Olive Oil (Oleum Olivæ) and Almond Oil (Oleum Amygdalæ Expressum) have no distinctive features and are good examples of the so called primary fats, as each contains about 70 per cent of oleic acid, as olein, with 30 per cent of palmitin and stearin. They are used principally for these fats, the purity of which depends on the condition of the fruit and care in extracting the oil. Being free from extraneous matters these oils are admirably suited for use in ointments and soap making. The U S P Sapo (common Castile Soap) is made from olive oil and sodium hydrate. The mottled appearance of the old soaps was due to the minute quantity of iron in the water used in making the soap. The U S P Sapo Mollis (soft soap), made from linseed oil, shows the difference in the oils. The fact that one is hard and the other is soft is due to the alkali used, as has been stated.

Cottonseed Oil—Cottonseed oil does not differ much from the preceding oils after it has been purified, in fact much of the "olive oil" sold is cottonseed oil. Cottonseed oil contains a large amount of palmitin and stearin and forms the basis for the commercial articles known as cottolene and lard compounds.

Lard—Lard (Adeps) is the name applied in commerce to almost any mixture of grease, and it seems that most of the pharmacists have the same idea, and are unaware that there is a standard established for this article, for the substance they dispense resembles that sold by the grocer and market man. Lard should be a mixture of stearin, palmitin and olein and not these fats in different stages of decomposition. The U S P requires that only the abdominal fat of the hog be used in making lard, while commercially any fat is used. Adeps Benzoinatus is intended to remedy the difficulty by adding an antiseptic to prevent decomposition and perfume the lard, but it is not as good as pure lard, for it often covers a slight amount of rancidity.

Suet—Suet (Sevum Preparatum) does not differ much from lard chemically except in the odoriferous principles. It is made from the abdominal fat of the sheep.

Tallow—Tallow is not recognized in the U S P, but is used in the lard compounds with cottonseed oil. It is obtained from the internal fat of the beef.

These oils and fats are not firm enough to form ointments, so beeswax (Cera alba and flava) and spermaceti (Cetaceum), are added in sufficient amounts to bring them to the required consistency. Their chemical nature is similar so the only effect produced is in raising the melting points of the mixtures. We use these animal and vegetable fats as vehicles to carry active principles which we wish to apply to the surface of the body for the purpose of producing systemic effect. The mineral fats are used only when local action is desired. The resulting compound is called an ointment or a cerate, according to its consistency. Ointments are soft, cerates are firmer.

The U S P gives a formula for an ointment (Unguentum) as follows:

Cere flavæ	5v	20
Adipis benzoinati	5ss	80

The German Pharmacopœia gives a different mixture, which will help illustrate the fact that we can obtain the same degree of consistency by different methods.

Cere flavæ	3i	30
Olei olivæ	5viiss	70

We should remember then that the word Unguentum has a definite meaning and indication. It should not be written Unguentum Simplex, for the last word is superfluous.

(This subject is to be continued.)

Iodin in Granular Pharyngitis

In cases of middle ear catarrh associated with granular pharyngitis, W L Ballenger, Chicago, employs the following formulas:

R	Tincture iodi	m	xlvi	3/5
	Glycerin q s ad		℥i	30
M. Sig	Apply to pharynx with swab once daily			

R	Iodoformi	gr 1	06

Cause of Death After a Fall.

The St Louis Court of Appeals says that in the case of *Johnson vs Continental Casualty Company*, the insured, a motorman, met with a fall in his home and the injuries then received were said to have caused his death two weeks later. According to witnesses who saw the accident, he had gone from one room of his home to the other to get a drink, and, as he went back, fell against a dresser having a marble top and from thence to the floor. The court holds that if either traumatic pneumonia or cerebral hemorrhage ensued as the result of the fall, and the insured died in consequence of the disease, his death was caused proximately and solely by accidental violence within the meaning of the policy. It says a physician testified that the patient must have died from one of those causes, but which one could not be known without knowing the patient's temperature at intervals, his other symptoms preceding death, and whether he had any prior diseases, that, if he was in good health before the accident, in the opinion of the witness, he must have died of one of said ailments. The value of the physician's testimony was to be determined by the jury. The court found nothing which appeared to it to be incredible in what he swore to. No doubt it was possible for the insured to have died of some ailment unconnected with the accident and which he was afflicted with prior to the accident or contracted subsequently, but whether he did or not was, on the evidence adduced, a fact to be found by the jury. Demonstrative proof that he died solely in consequence of the accident, hardly could be made. On such issues evidence can not go beyond producing that degree of conviction in reasonable minds on which men are accustomed to decide and act in ordinary affairs. All possibility of mistake can not be excluded.

Non Experts May Testify to Symptoms But Not to Diseases.

The Court of Appeals of Kentucky holds, in *Illinois Life Insurance Company vs De Lang*, that no witness, not an expert, should be allowed to state his opinion that the insured had consumption or did not have it, or that he was in good health or bad health. The non expert witnesses may detail the facts that they know. They may tell what symptoms they saw or observed, but the jury can judge as intelligently as the witnesses as to what the symptoms indicated. The court also holds that the insured's wife was a competent witness for the plaintiff. She might testify as any other witness as to the health of her husband, or as to what he did or as to any other matters not involving communications between her and her husband growing out of the marital relation. The court sees no objection to the testimony which she gave in the case to the effect that her husband did not have this or that symptom at a certain time.

Exhibition of Amputated Leg to Jury

The Court of Appeals of Kentucky says in *Ford vs Providence Coal Company*, that it was assigned as error that the trial judge refused to permit the plaintiff to exhibit his injured leg to the jury, but as the leg had been amputated this ruling was not prejudicial. However in the trial of personal injury cases the court goes on to say it is competent for the plaintiff to exhibit the injured member to the

jury, and this he may do on the request of his counsel or of the adverse party—provided that the exhibition does not violate any rule of propriety or decency. Whether it does so or not is, of course, a question that must be left largely in the discretion of the trial judge. No objection of this kind could be urged in this case, as the exhibition of a man's leg that has been amputated could not be considered at all improper. Evidence of this character is really the best evidence obtainable of the extent and character of the injury that the person seeking damages has sustained, and the jury has the right to be aided in making up their verdict by a personal view of the injured member.

Expense of Protecting Public from Insane Pauper

The Supreme Judicial Court of Maine holds, in the case of *Inhabitants of Town of Casco vs Inhabitants of Town of Lanington*, that the expenses incurred by a town to protect its inhabitants or the public from danger of injury by insane paupers are not recoverable under the pauper statute, nor under the contagious diseases statute, which authorizes the recovery only of the expenses of relieving persons destitute, and of their removal or burial. The statute authorizing recovery of expenses of preventing the spread of contagious diseases by paupers is not applicable to a case of insanity.

Homicide by Abortinist—"Private Papers"—Evidence

The Supreme Court of Illinois says in *Clark vs People*, that Section 3 Division 1 of the Criminal Code of Illinois reads: "Whoever, causes any woman, pregnant with child, to abort or miscarry, or attempts to procure or produce an abortion or miscarriage, unless the same were done as necessary for the preservation of the mother's life, shall be imprisoned, or if the death of the mother results therefrom, the person procuring or causing the abortion or miscarriage shall be guilty of murder." It was insisted that this statute does not provide that if the death of the mother results therefrom, the person attempting the abortion or miscarriage shall be guilty of murder, but only in case a person actually causes the abortion. But the court believes the fair and reasonable construction to be that when death results either from an abortion or an attempt to produce an abortion the person responsible should be held guilty of murder.

Furthermore the court is also of the opinion that under the last part of Section 145 of the Criminal Code, which reads, "where such involuntary killing shall happen in the commission of an unlawful act, which in its consequences naturally tends to destroy the life of a human being, or is committed in the prosecution of a felonious intent, the offense shall be deemed and adjudged to be murder," the accused under the indictment in this case could be held for murder.

Some of the counts of the indictment charged the instrument to have been thrust into the "body and womb" and other counts into the "private parts and womb" and it was insisted that there was fatal variance in that the proof showed that the instrument was not thrust into the womb but into the bladder. But the court thinks that, apart from technical distinctions the term "private parts" sufficiently describes the female organ of generation and its immediate vicinity not only for that particular and limited portion anatomically known as the womb but for the vagina the urethra and lips of the womb. It says that the fact that the instrument inserted through the lips of the private parts entered the urethra and pierced the bladder instead of passing up the vagina and into the womb did not in any way mislead the accused.

The court also says that evidence to convict of a crime such as here charged in the absence of the testimony of the victim is almost always circumstantial and hence the question of the admissibility of collateral facts in evidence is often to be determined by the nature of each case. And it holds that on a trial for an offense such as charged in this indictment intent is an essential ingredient and it is competent to hear the declarations of one on trial for the same offense as to the effect that she was in the habit of doing such work.

Liability for Communication of Smallpox by Agent

The Court of Civil Appeals of Texas affirms, in *Missouri, Kansas & Texas Railway Company of Texas vs Raney*, a judgment for \$150 in favor of the latter party, who brought the action to recover damages for the company's ticket agent communicating smallpox to him and his wife. It holds that the company, under the common law, owed to the individuals composing the public who dealt with it the duty to keep them from having contagious diseases communicated to them by its agent while they were dealing with it through such agent.

The testimony of a physician to the effect that, according to his best recollection, he had seen and examined the agent, and that he then had smallpox, and that he so told him, the court holds was sufficient to support a finding of the jury that the agent had smallpox and knew it when the plaintiff bought tickets of him for himself and wife. It also holds that the testimony was sufficient to support the finding of the jury that the plaintiff contracted the smallpox from the company's agent, when, in so far as the evidence showed, such agent was the only person to whom the plaintiff was exposed who had the disease, and the evidence showed that the plaintiff contracted it within the usual time after such exposure.

The company's contention that knowledge on the part of its ticket agent that he had smallpox at the time he sold the tickets to the plaintiff would not constitute knowledge on its part of such fact, the court does not think sound. In its opinion, the agent at the time the plaintiff was exposed to him, being the ticket agent of the company and in the discharge of the duties incumbent on him as such agent, and the plaintiff being present for the purpose of transacting business with him in the line of his duties to the company, and the agent at the time having the contagious disease of smallpox, and knowing that he had it, his knowledge became that of his principal, the railroad company.

Furthermore, the court holds that the act of the company's agent in communicating to the plaintiff smallpox was the proximate cause of the plaintiff's wife contracting the disease, and his being quarantined on account of his wife's having smallpox. It says that the company, through its agent, knew from the attending circumstances that the tickets sold were for the plaintiff and his wife, and of that relationship between them, and that, in their companionship and association with each other during the trip on the cars and while visiting in Alabama, they would not only be in close proximity with each other, but frequently in personal contact with each other, so that if the husband contracted the disease of smallpox from the agent of the company, it was natural and probable that he would communicate it to his wife, and such a result was one that might reasonably have been anticipated by the company through its agent.

Therefore, the company, having notice through its agent, at and prior to the time the plaintiff was exposed to him, that he had the smallpox, and said agent having communicated said disease to the plaintiff and his wife, the court holds that the company was liable to the plaintiff for the damages sustained by him as the direct and proximate results of such wrongful act of its agent. Nor does it think the losses sustained by the plaintiff in his business on account of patrons being kept away through fear of contracting the disease were too remote to be recovered.

Presumptions and Proof Requirements as to Suicide

The Supreme Court of Minnesota holds, in the case of *Lundahl vs Supreme Court Independent Order of Foresters*, an action to recover the amount of a benefit certificate that the defense being suicide, (a) The burden of proving that the deceased committed suicide was on the defendant. (b) The presumption is against suicide. (c) If the known facts are consistent with the theory of natural or accidental death the presumption which the law raises from the ordinary motives and principles of human conduct requires a finding against suicide. (d) When circumstantial evidence is relied on the defendant must establish facts which exclude any reasonable hypothesis of natural or accidental death.

The court says that it is settled that on the issue of suicide the burden is on the defendant, who asserts the fact, to prove the same by a fair preponderance of the evidence. In all legal discussion the existence of certain qualities in human nature are presumed. Common experience teaches that the love of life, the instinct of self preservation, respect for the laws of the land, and the principles and teachings of religion are ordinarily sufficient to prevent a person from destroying his own life, and therefore, when the facts proved with reference to death admit equally of the inference that the death resulted from accident or suicide, the presumption is that death was accidental.

As long as the evidence is consistent with the theory of accidental death, the presumption against suicide is controlling. The issue being the fact of suicide, it is for the defendant to prove this ultimate fact by a fair preponderance of the evidence. It starts with the burden of overthrowing the presumption that a person does not voluntarily destroy what is commonly regarded as the most precious of all possessions, life itself. When the fact of death appears, the law presumes that it must have resulted from causes which were not voluntarily brought about by the deceased. Death may result from innumerable causes. The facts of a case may suggest accidental shooting, poisoning or drowning. If the evidence is consistent with the theory of either, the presumption which the law raises from known and recognized controlling forces of human nature requires the conclusion that the death was accidental. If the known facts are consistent with a cause of death which does not involve self destruction, that cause must be accepted.

After all the hypotheses which are consistent with an innocent or accidental death are eliminated, the conclusion of suicide may then be drawn. The burden is on the defendant to show that the circumstances and conditions are inconsistent with any other reasonable cause of death than that of suicide, that is, it must eliminate and disprove all other causes of death which are consistent with the evidence before the jury is justified in inferring that the deceased committed suicide. The ultimate fact of suicide is thus shown by the proof of certain evidentiary facts which are inconsistent with the theory of accident or natural death, or by proof of the non existence of facts which would justify the inference of accident. But the ultimate fact is required to be proven by a preponderance of evidence only, and this rule is in no way affected by the subsidiary requirement that the defendant must by its evidence exclude every other reasonable theory for accounting for the death.

1 New Operation for Epispadias—Beck describes an operation for epispadias which he employed successfully in one case. The funnel like appearance of the urethral orifice over the pubic bone suggested to Beck to dissect the surrounding walls, including the whole urethral gutter, in the same way that a hernial sac including the cord is liberated and mobilized in the radical operation for inguinal hernia. This plan was carried out by making a continuous incision around the funnel as well as the outer margins of the urethral gutter the aim being then to shell out a coherent canal which is meant to be the new urethra. The steps of the operation are described in full.

2 **Pneumonia**—The best course to pursue in the treatment of pneumonia, according to Burt, is to secure for the patient repose of mind and body, a simple, but nutritious diet, an unlimited supply of fresh air and sunshine, and such hygienic measures as are necessary to maintain the strength of the patient and to alleviate the severity of symptoms and avert complications as far as possible. He advises promoting the intrinsic capacity of the fluids and cellular elements of the body to overcome the virulence of the infection, and suggests that this may be done by the injection of physiologic saline solution. Care should be observed not to inject more than one dram of the solution to each pound of the body weight, in each quarter of an hour.

4 **Buttermilk as Infant Food**.—Strauch has had excellent results accrue from the use of buttermilk in the feeding of infants. His experience includes more than 20 cases, mostly of malnutrition, resulting from chronic gastrointestinal disturbances, with occasional acute exacerbations up to the intensity of cholera infantum, one case of habitual vomiting (pyloric spasm), one case of icterus catarrhalis, one prematurely born child, and some cases of *alaitement mixte*. Some of these cases had not responded to other methods of feeding and treatment.

5 **Carcinoma of Uterus**.—Thienhaus urges careful and conscientious efforts on the part of the general practitioner to diagnose carcinoma of the uterus, resorting to the microscope in dubious cases. He sounds a note of warning against the indiscriminate cauterization of what appear to be simple erosions of the cervix without first confirming the diagnosis with the microscope.

7 **Crusade Against Tuberculosis in Germany**.—Locke discusses very fully the principles underlying the crusade against tuberculosis now being carried out in Germany. He says that several fundamental considerations, which make such a general movement possible, should be borne in mind. First, the entire kingdom of Germany is under uniform laws, those pertaining to disease and the general health of the people being controlled by a national board of health presided over by a cabinet minister. Through this imperial health bureau a most exhaustive investigation of the existing conditions has been carried out and relief measures promulgated, second, the scientific spirit which permeates German medicine is largely responsible for the effectiveness of this organization in that it has, step by step, pointed the way to success, third, on compulsory insurance against sickness and invalidity has placed at the disposal of the authorities immense funds which could in part be directly applied to the erection and maintenance of sanatoria, convalescent homes, care of the consumptive's family, etc.

8 **Diffuse Peritonitis Following Appendicitis in Children**.—Smith reports seven cases of diffuse peritonitis, following appendicitis, occurring in children, from 3 to 8 years of age, a study of which convinces him that appendicitis in children exhibits certain features not altogether common in adults. Four of these children died. The most striking feature in all of these seven cases was the fact that the pathologic conditions found at operation were out of all proportion to the duration of the illness. In three of the cases, the peritonitis was so extensive as apparently to involve the entire greater cavity with an average duration of less than 48 hours from the appearance of the initial symptoms. It was a noticeable fact that in five of the cases the perforation in the appendix was large, that is, as great in diameter as a split pea.

9 **Extraordinary Blood Findings**.—The characteristic feature of the blood in the case reported by Van Nuy was the presence of large basophilic phagocytic cells capable of amoeboid motion. There were two varieties of these cells. One was a large, mononuclear cell, with granular, fragile, often vacuolated cytoplasm, the nucleus being large, oval or bean shaped, often vesicular, and sometimes containing a pale, yellow brown nucleolus. The other type was a multinuclear, phagocytic, giant cell, with long fantastic streamers of protoplasm. The patient had suffered from dyspnea, severe constipation, chronic bronchitis and some edema of the feet and bases of the lungs. He had a fairly compensated aortic regurgitation, his liver and spleen were enlarged considerably. In the region of the descending colon were two hard masses, egg shaped, deep and immobile. On the day of his admission to the hospital the patient, a Russian Jew, butcher by occupation, passed nineteen feet of the beef tapeworm after one dose of castor oil. Eggs of *Trichocephalus dispar* were also present in the stools.

10 **Cervical Adenitis**.—A careful study of 300 cases of cervical adenitis leads Donoghue to draw the following conclusions: 1 Enlarged glands of the neck are not, primarily, tuberculous, and bear the slightest relation, if any, to general or pulmonary tuberculosis. 2 They are due to a mixed infection of pus producing bacilli. 3 They will quickly resolve if the source of the infection is removed before the glandular tissue becomes disorganized. 4 If disorganization takes place, the gland should be poulticed until the gland is practically liquefied. It should then be opened by a stab puncture emptied and drained by a "Briggs canula." 5 Cases seen late, with a large mass of partially calcified and partially disorganized glands present, call for a thorough and extensive dissection.

12 **Primary Ligation of Vas Deferens Before Operations on Testes**.—An exhaustive study of tuberculosis of the genito-urinary organs has convinced Walker that during the excision of a testicle the manipulation necessitated is more than likely to force tubercle bacilli along the healthy vas into the blood or lymph vessels and thus produce a general infection. In order to eliminate this danger Walker advises preliminary ligation of the vas deferens and its accompanying vessels high in the groin. After the testis has been freed in the usual way the vessels should be cut at the point of primary ligation and the cord freed still higher up and gently pulled as far as practicable out of the external ring before it is ligated and cut.

13 **Cancer of Vulva**.—Johnson reports a case of primary epidermoid carcinoma of the labium and vulva, occurring in a woman 69 years of age. The labium, clitoris and three-fourths of an inch of the urethra were removed. For five years the patient remained well. Then the tumor appeared on the opposite labium and it was removed two years later. Seven years after the original operation. Nine months after the second operation the patient reported herself in good health.

14 **New Method of Treating Appendicular Stump**.—In the method described by Denny the appendix was freed the meso-appendix ligated and a purse string suture applied in the cecum in such a way that two loops are left which with the two ends at the starting point, divide the circle about the appendix into three equal spaces. A smooth jawed Ferguson clamp is applied to the appendix, and distal to this clamp the appendix is severed with a thermo-cautery. The stump is inverted and invaginated into the cecum and the ends of the ligature previously applied are pulled until the loops disappear.

17 **Cataphoric Table.**—Massey describes a cataphoric table which he has devised, and which permits of a perfect control of the 110 volt direct street current in the operating room

18 **Cataract.**—Weeks divides cataracts into four varieties 1, Cataracts that form early in life, 2, cataracts which develop by the formation of fissures in the cortex, 3, cataracts in which the opacification appears in the center of the lens, and 4, zonular cataract. Extraction of the cataract in the four types mentioned, if done when most propitious for the welfare of the patient, would be performed by Weeks in the first type as soon as liquor Morgagni appeared between the lens capsule and the lens substance, in the second type, at the convenience of the patient after vision is reduced below that necessary for the ordinary vocations of life, in the third type, when useful vision has been abolished, and the lens is appreciably shrunken, in the fourth type, at the convenience of the patient after vision is reduced below that necessary for ordinary uses

19 **Pubiotomy.**—Norris reports a case in which pubiotomy was done instead of an elective Cesarean section, with excellent results. Both mother and child lived. Norris says that it seems to him that in the hands of the average surgeon in private practice pubiotomy is safer than Cesarean section

21 **Eosinophilia and Trichiniasis.**—Ottenberg publishes the histories of eight cases of trichiniasis. Although the presence of trichinae was demonstrated in only three of the cases, the clinical evidence was sufficiently striking to permit of making a positive diagnosis. The combination of eosinophilia with the other characteristic symptoms, viz, edema of the face, which occurred in six of the eight cases, muscular pains, present in all, though only very pronounced in two, and fever, present in seven cases, makes a clinical picture which could hardly be presented by any disease other than trichiniasis

38 **Natural vs. Mechanical Ventilation of Hospitals.** P. H. Ball. U. S. Public Health and Marine-Hospital Service.

34 **Penetrating Wounds of Abdomen.**—Wreden says that active operative intervention when admitted by the general condition of the wounded, and the surrounding circumstances, is indicated in all cases of perforating wounds of the abdominal cavity, with the exception of wounds inflicted with the modern small caliber undeformed rifle bullet. In these cases expectant treatment gives the best results. He emphasizes that all those wounded in the abdomen need full rest, at least for one week after the infliction of the wound. He has found morphin a powerful remedy in facilitating the cure of penetrating wounds of the abdomen.

35 **Multiple Gunshot Wounds.**—LeWald reports the case of a Filipino who was shot four times, at close range, with a regulation Colt's revolver caliber 38 and was finally stunned by a blow on the forehead by the end of a carbine. The first bullet entered the chest near the right nipple, passed upward, backward and outward, perforated the lung, and made its

exit through the back, passing through the outer edge of the right scapula. The second bullet entered the chest near the left nipple, perforated the lung and lodged in the back of the subcutaneous tissues. The third bullet entered the chest near the left shoulder, passed downward and backward, perforated the left lung and lodged in the muscles of the back. The fourth bullet entered the palm of the left hand, passed through the subcutaneous tissues, and made its exit through wound in the anterior surface forearm. The patient was discharged cured at the expiration of 28 days.

36 **Fracture of Skull.**—In the case reported by Waterhouse a very extensive lesion resulted from a comparatively slight traumatism. A man fell down a basement stairs and struck on the concrete floor. Apparently he was intoxicated at the time. He was picked up unconscious, and at the time there was rather free hemorrhage from the left ear. The man died about three and a quarter hours after receiving the injury. A necropsy was made. Large clots of blood were found at both sides of the head, both between the dura and the skull and between the dura and the brain. Both cerebral lobes showed punctate hemorrhages. The anterior tips of the frontal lobes were infiltrated with blood. Starting at the region of the occipital protuberance was a V shaped fracture of some size, and there was also a transverse, jagged fracture across the orbital plate of the frontal bone on both sides and a transverse fracture across the ethmoid bone.

39 **Mycosis Fungoides.**—McVey reports a case of this kind occurring in an infant. The tumors were situated on the left eye and left cheek. On other portions of the body there were circumscribed erythematous patches. The father of the child had had such an eruption over his body when he was an infant, but after his development into manhood the disease disappeared and did not return. The child was given the syrup of the iodid of iron, 5 drops, three times a day, and the oleate of bismuth was applied locally. The Finsen light was also used for 15 minutes each day. The child died three months after coming under observation.

40 **Appendicitis.**—Murdock reports five cases of appendicitis to illustrate that often the only symptoms manifested are the initial pain in the abdomen, elevation of temperature, and increased pulse rate, that is, there is almost a total lack of grave symptoms to justify a laparotomy.

44 **Sarcoma.**—Perkins reports a case of small round celled sarcoma occurring in a woman aged 37, in which a portion of the ileum, the entire cecum and ascending colon, and a portion of the transverse colon were resected. The diagnosis was confirmed on microscopic examination. The patient recovered and has remained well for nine months.

46 **Skin Grafting.**—While Roehrig's conclusions based on his experience are wholly favorable to the employment of the Reverdin grafts, he concedes that there is at least one instance in which the Thiersch flap method is of equal, if not of su-

perior advantage because of improved facility of operation, and that is when a convenient amputation is taking place, either on the same or some other patient and the skin of the amputated limb can be employed advantageously. However, the advantage gained is merely in time saved and not in additional effectiveness in results.

49 Excision of Gasserian Ganglion—In separating the dura from the bone, Williams deliberately tore the middle meningeal artery as it emerged from the foramen spinosum. The hemorrhage, which was profuse, was quickly and absolutely controlled by forcing into the opening a conical plug of wood, previously prepared by repeated sterilization for this particular purpose. This freedom from hemorrhage greatly facilitated the approach and free exposure of the ganglion, which was eventually removed. The operation has given the patient absolute freedom from pain for over a year.

50 Treatment of Chronic Rheumatism—Stuver has found the galvanic current exceedingly beneficial in many cases of chronic rheumatism. He employs a current of from 5 to 20 mp, applying it from 20 minutes to half an hour. He says that these results can be increased if a thin layer of cotton wet in a solution of cocaine be applied over the skin under the positive pole.

51 Id.—Heisen considers massage most useful in the treatment of chronic rheumatism.

55 Chorea—Giesy reports a case of chorea that was complicated by marked and persistent tympanitis, a primary eruption, slight meningeal symptoms and endocarditis. The case suggested from time to time mild scarlatina, parasitism, meningitis and chorea. Giesy suggests that perhaps the choreic movements were caused by a toxemia resulting from improper intestinal metabolism.

56 Gummatous Meningitis—Ewing reports a case of this kind occurring in a woman aged 39, twice married, who had four children living, all by the first husband. After her second marriage she aborted many times. About three months after the marriage a sore appeared on the external genitals, which was treated locally with good results. Ten years afterward she manifested symptoms of meningeal disease, such as head ache, sleep disturbances, muscular weakness, impaired memory and fleeting paresis, which led to the diagnosis of gummatous meningitis. Under the most intensive antisyphilitic treatment the patient began to improve and continued to improve until she finally disappeared from observation.

57 Deep Rectal Abscesses—Frankfurter reports two cases of this kind and emphasizes the fact that in obscure cases of trouble in the pelvic region the patient should be examined thoroughly and kept under closer observation until a positive diagnosis is made.

58 Cough—Buckwalter discusses the extrapulmonary causes of cough which develop in consequence of pathologic changes in the upper respiratory tract and disturbances in its function. He reports several cases in point.

59 Treatment of Chronic Joint Disease—Edmonson urges early diagnosis, suitable treatment for the individual case and maintenance of the general health of the patient by means of diet, tonics and hygiene.

62 Eartire—Musson suggests that there may be an analogous condition of fatigue of the auditory apparatus with important reflex manifestations similar to evestrian. He suggests for this condition the term eartire. Neurasthenia, head

ache and insomnia, he says, may be caused by maladjustment of the muscles or ossicles, or the long continued registration of unrhythmical sounds by even a normally adjusted ear may greatly fatigue the cerebral auditory centers and cause the manifestations of symptoms of eartire. [Eartire was discussed editorially in THE JOURNAL, July 8, 1905, page 109.]

- 65 *Suggestions for Reorganization of Hospital Out Patient Departments. R. C. Cabot Boston.
66 Danger of Sending Consumptives to the Country E. V. LaMotte Baltimore.

65 Reorganization of Dispensary Service—Cabot's paper is summarized as follows: 1 Dispensary work is part of public health work, and should be done as well as are the examinations made at state and municipal laboratories. 2 To attend to the mass of details on which good treatment depends a nucleus of permanent paid employes is necessary. This paid staff should consist at present of nurses trained for the purpose. 3 These paid employes should understand the physician's directions and see that they are carried out in the patient's home, reporting back to the physician any data concerning the domestic and social conditions which bear on the diagnosis and treatment of cases. 4 Either through these nurses or through social workers on hand daily at the dispensary the hospital should obtain for its patients the full benefit of any resources—moral, educational and financial—which the community affords. This help is especially important in "functional" cases, which make up over one third of the medical outpatient clinics. 5 Through these means and by the development of mechanical and psychical measures and hydrotherapeutics our dispensaries can be freed from the twin abuses which now limit their therapeutic usefulness: (a) Hurry and consequent makeshift, (b) wholesale drugging.

68 *Acute Leukemia C. P. Emerson Baltimore.
69 Benjamin Rush as Materialist and Realist L. W. Riker Baltimore.
70 Multiple Tumors in Dog E. K. Cullen Baltimore.

67 Uniform Nomenclature of Diseases—A new classification of diseases of the gastroenteric tract is suggested by Rotch. The diseases are divided into gastric and enteric, and these again into developmental, non infectious and infectious. The further subdivisions of the non infectious groups are based, as far as possible, on the origin of the condition, such as mechanical, functional, new growths, traumatic and ulcers. The classification is presented in full as follows:

68 Acute Leukemia.—Emerson reports three very interesting cases of acute leukemia 1 A case of acute lymphatic leukemia, without enlargement of lymph glands or spleen, with localized involvement of the bone marrow, and with very many white cells that were soluble in dilute acetic acid. 2 A case of acute leukemia, resembling a septicemia, with the leucocytes almost all achromatophilic 3 A case of acute leukemia with leucopenia—aplastic leukemia

- 90 *Hemilingual Atrophy of Traumatic Origin S E Jelliffe New York

82 Herpetic Inflammations of Geniculate Ganglion.—Hunt brings together three separate groups of cases which he believes constitute a new and distinct clinical entity The pathology of the affection is identical with that of herpes zoster of which it forms a part, the distinguishing features of the clinical picture depending entirely on the ganglion involved and the nature of the structures surrounding it. Hunt believes that the geniculate ganglion may be the seat of the herpetic inflammation The clinical types of the affection are herpes auricularis, herpes auricularis with facial palsy, and herpes auricularis with facial palsy and auditory symptoms The zoster zone for this ganglion is found in the interior of the auricle

and in the external auditory canal Hunt reports two characteristic cases in full

83 Brain Tumor Symptom-Complex.—That conditions other than brain tumor may cause symptoms, general as well as focal, simulating brain tumor is shown by Hoppe, who reports three cases One of his patients died of pulmonary tuberculosis after having been under observation for 10 years for a supposed cerebellar tumor At the necropsy the brain was found to be normal in every respect. The examination of the brain included macroscopic as well as microscopic study There were no adhesions or any other lesion of brain or membranes Two patients are alive and well after two years and thirteen and a half years respectively In these two cases the symptoms also pointed to brain tumor and the diagnosis was made accordingly Therefore, Hoppe urges that clinicians should not be too pessimistic in their prognosis of brain tumors, especially in the cerebellar cases, and that they should not be too hasty in the recommendation of surgical intervention until therapeutic measures have been given a long and thorough test

84 After Care of the Insane.—Meyer gives a brief report on a movement which was inaugurated in New York state for the purpose of the after care of needy persons discharged from hospitals for the insane

85 Experiment in Civic Medicine.—Schwab outlines the main purposes underlying the organization of a commission in St. Louis whose function it is to cultivate a better standard of expert medical testimony and to train a group of experts in mental questions for service in the courts The central idea of the experiment is that all expert testimony should be given on the question at issue and should have nothing whatever to do with one side or the other in the actual legal test of a case In other words, it should be the expert's duty to inform the court on questions of the proper interpretation of facts lying within the limits in which expert knowledge is required. The commission consists of four members, and its report is transmitted to the circuit attorney, who, with the assistance of two judges in the criminal courts, appoints the commission The commission has no legal or official position and exists merely as a matter of convenience to the court The report of the commission is without bias or prejudice

87 Migraine and Hemianopsia.—Whether attacks of migraine, in the absence of disease of the vessel walls, are capable of producing permanent changes in the nervous structures is the point discussed by Thomas As the result of careful study of several cases he concludes that attacks of migraine may result in an area of softening in the brain, which shows itself by a permanent paralysis, aphasia, or hemianopsia, and that in most instances this is due to the attack favoring a vascular lesion in persons who have already disease of the walls of the blood vessels, but that in certain cases the vascular lesion may occur in young persons whose blood vessels are in all probability in a normal condition In all cases of organic disease of the brain, coming on during an attack of migraine extreme caution is necessary before ascribing even an exciting rôle to the migraine, as it is much more common to find independent organic disease of the blood vessels which would account for the organic disturbance in persons who have suffered from migraine yet a few cases remain which can hardly be explained in this way, and justify the statement made by Charcot and others that the transient hemianopsia or aphasia seen occasionally in this disease may become permanent

88 Peripheral Facial Diplegia with Palatal Involvement.—Jacoby reports four cases under his observation, three of which showed palatal palsy

90 Hemilingual Atrophy.—Jelliffe reports a case of simple hemilingual atrophy due to injury to the hypoglossal nerve at its exit from the skull

9 *Class Incidence of Cancer D Heron.
10 *Insanity Its Causes and Increase. G H Savage

1 Thoracic Aneurism.—Oliver discusses the clinical history of this condition, which he believes is in at least 50 per cent. of the cases due to syphilis. Other causes mentioned are sudden strain and injury, alcohol, and previous disease of the vessel walls. Rest in bed and quietude, together with a restricted diet, are mentioned as essentials in the treatment. Iodid of potassium is said to give great relief, but does not produce a cure. Speaking of galvano-puncture, Oliver says that in one case of subclavian aneurism thus treated, the result was satisfactory, until, as the result of friction, the aneurism redeveloped and burst into the surrounding tissue.

2 Aortic Disease.—Digitalis in combination with nitroglycerin is recommended very highly by Rankin in the treatment of aortic disease. He says that the nitroglycerin prevents increase of peripheral resistance and so robs the digitalis of that influence on the arterioles on account of which its administration is supposed to be contraindicated. Rankin is a firm believer in the efficacy of digitalis in the treatment of aortic disease when compensation has failed.

3 Surgical Aspects of Hemophilia.—Rest and pressure are said by Groves to be the two essentials in the treatment of hemophilia from a surgical point of view. When the joints become swollen they should be bandaged firmly, and kept at rest until the effusion subsides. It is by neglect of this treatment that the ligaments become stretched and weakened, and the changes of osteoarthritis hastened. Groves reports three cases of hemophilia which illustrate the hereditary nature of this affection. In two of the cases, ischemic paralysis resulted from the disease.

4 Anomaly of Heart.—The patient whose case is reported by Mann was 35 years of age, and presented the usual appearance of one suffering from chronic heart disease. The area of cardiac dullness was increased, the cardiac impulse was more extensive than usual, and the apex beat was difficult to locate. There was no thrill. The first sound was replaced by a loud, rushing, systolic murmur, which extended over the whole cardiac area. The center of the impulse was about the fifth interspace, a little within the nipple line. The heart beats were tumultuous and irregular, the veins were overfilled, and those in the neck pulsated. There was intense dyspnea and cyanosis with general edema and effusion into the serous sacs. The patient died. At the necropsy it was found that the heart had only one ventricle from which emerged two arterial trunks, and into which opened the mitral and tricuspid orifices, all in their normal positions. The auricular portion of the heart presented nothing abnormal, except that the foramen ovale was patent. The heart weighed 28 ounces. The man had never been cyanosed until the last three weeks of his life, and he had never been ill in bed until his final illness. When a boy, he had had attacks of breathlessness, cough or headache, which lasted for a day or two. He was unable to join much in boys' sports.

5 Calcium Salts as Cardiac Tonics.—Brunton believes that the free use of calcium salts has a tonic action on the heart in cases in which there is a tendency to cardiac failure. He has given calcium chloride in doses of from five to ten grains, dissolved in water, every four hours, with most excellent results in cases of impending cardiac failure in pneumonia. The disagreeable saline taste of the salt is covered by one minim of the elixir of saccharin, containing 1/20 of a grain of saccharin for each ten grains of calcium chloride. The mixture is given in water or milk and is said not to interfere with the use of other remedies. The salt has also proved efficacious in cardiac disease, when the ventricular wall appeared to be losing power. In such cases, the lactophosphate or glycerophosphate of calcium may be employed.

6 Delayed Chloroform Poisoning.—Renton reports two cases in which symptoms of delayed chloroform poisoning were observed in adults four days after the administration of the anesthetic.

7 Chronic Peritonitis Causing Elephantiasis.—Bernstein and Price report a case of general anasarca, edema and elephantiasis, the result of a chronic peritonitis. At the necropsy, there was found prominent perihepatitis, perisplenitis and peritoneal fibrosis surrounding the lymphatics at about the level of the receptaculum chyli. Below this, was a varicose condition of all the lymphatics and edema and hyperplasia of the parts drained by these affected vessels, but not of the mesenteric lymphatics or lacteals.

8 Diet and Thyroid Activity.—Fordyce carried on a series of experiments on rats, with a view to ascertaining whether or not diet had any effect on thyroid activity. The diet given consisted of (1) Bread and milk, (2) fresh milk (3) the same milk pasteurized, (4) the same milk boiled for thirty minutes. In all cases an unlimited supply was given. Fordyce found that the variations in the series of glands examined corresponded with the differences in the diet. In the milk fed rats the gland vesicles were large and well filled with colloid material. The lining cells were small, with deeply stained nuclei. In the glands of the bread and milk fed rats, the vesicles were very markedly smaller and the amount of colloid present very considerably less. The lining cells were columnar.

9 Class Incidence of Cancer.—Heron says that there is always a substantial correlation between the cancer death rate and social status—that is the incidence of cancer is most heavy among the well-to-do classes.

10 Insanity.—Savage claims that there is no such disease as insanity—that it is a negation and depends more on the social than on the medical conditions—that certain forms are due to direct brain decay others to brain intoxication and others to morbid habit or morbid surroundings or are the

natural but morbid mental growths occurring in certain unstable individuals

11 Infective or Toxic Conditions of the Nervous System.—The following deductions are made by Buzzard from his investigations

1 Organic and inorganic substances when present in the lymph spaces of nerves tend to be carried centralward toward the spinal cord and meninges, and especially through the posterior spinal roots 2 Entry into the spinal cord is made chiefly along the various septa within the lymph channels of the radial vessels and along the anterior but more particularly the posterior roots 3 The same substances within the spinal cord and its membrane appear to travel upward mainly between the meninges and along the central canal 4 The changes within the cord resulting from its bacterial or toxic infection through these lymph channels are somewhat patchy and irregular, affecting the gray and white matter alike, with a special incidence on the posterior columns 6 The morbid histologic processes consist of toxic changes in ganglion cells, blood extravasations, small round cell infiltration of the tissues and perivascular sheaths, some proliferation of neuroglia cells, and parenchymatous degeneration of the nerve strands

12 Renal Function and Surgery—In this, the first lecture on this subject, Walker takes up the estimation of renal function He says that as a measure of the total renal function the phloridzin and methylene blue tests are most trustworthy The phloridzin method is open to the objection that it is too easily influenced by slight variations in the renal function At present the methylene blue test is the method by which most trustworthy information can be obtained and appears to form a valuable addition to the clinical methods of estimation of the renal function

14 Insanity—Urquhart says that prognosis in insanity must proceed on a wide and careful review of the whole circumstances affecting the individual, who is in a degenerative condition physically and therefore mentally All that goes to make up that degenerative condition must be separately investigated and summed up The elements of prognosis are analytical and synthetical, and it is determined by the nature of the degree of the involvement of the organism in the widest sense If all the functions are involved, if the degenerative process is universal and intractable, the future of the individual is desperate indeed, if the defect is partial and amenable to treatment naturally the case is more hopeful as these limitations of involvement decrease

15 Medical Treatment of Congenital Pyloric Stenosis—Sutherland discusses the treatment of congenital pyloric stenosis by means of dieting and gastric lavage, and reports three cases that have come under his care, in two of which the treatment proved successful In the third case it became necessary to resort to stretching of the pylorus, but the patient died.

17 Colle's Fracture—Morton made a very careful radiographic study of 170 cases of what was diagnosed clinically as Colle's fracture In 155 cases the radius only was fractured, the ulna in 2 cases, both bones in 7 cases the trapezium in 1 case, no fracture detected in 5 cases, dislocation of wrist joint complicating fracture in 3 cases, fracture communicating with the wrist joint in 25 cases, fracture of the styloid process of radius in 20 cases of the ulna in 88 cases separation of one or both epiphyses in 11 cases

- 22 *Congenital Symmetrical Sinuses of Lower Lip H S Clogg

20 Hematuria in Infants.—Parkinson reports a case of infantile scurvy in which hematuria was the only obvious sign of the disease, although on closer examination other signs were discovered In another case, a congenital renal tumor caused hematuria, while in a third, hematuria followed scarlet fever In the latter case Parkinson found dry cupping over each kidney of great value in checking the hemorrhage

22 Congenital Sinuses of Lower Lip—The child, whose case is reported by Clogg, was born with a severe degree of bilateral hare lip and cleft palate, the premaxilla stood out prominently The latter was broken and bent backward, and the upper lip repaired over it The interesting condition was, however, seen on the lower lip On the upper surface of this lip on either side of the middle line was a papilla, the two papillae were symmetrical, and surrounding them in the form of a semicircle on the aspect toward the mouth was a groove, and leading from this furrow was a sinus, which passed downward into the lip for about a quarter of an inch. The two sinuses ended blindly, converging slightly, and were situated immediately beneath the mucous membrane of the lip Issuing from the sinuses was a mucoid secretion

24 Sphincter in Control of Bladder and Prostatectomy—It is well known that after prostatectomy, the control of micturition is usually somewhat abnormal at first, but quickly becomes apparently normal Ball thinks that this is probably owing to the compensatory powers of the compressor urethrae muscle He says that whether or not the internal sphincter of the bladder acts after suprapubic prostatectomy is a point which must be ascertained by necropsies on patients some years after the operation But it seems quite incorrect to argue, he says, from operations on patients with enlarged prostates, that the chief sphincter of the bladder normally lies in the membranous urethra

25 Treatment of Hemoptysis—Hichens advises putting the patient to bed in a cool, airy room, in a propped up position, giving him an injection of morphia, letting him have some turpentine to inhale, and reassuring him of a favorable outcome The patient should be put on a calcium chlorid mixture, have his bowels kept well open by a saline purgative, have a cool and partly dry diet, and ice to suck to relieve thirst If the hemoptysis is persistent, or recurrent, Hichens would use nitroglycerin

26 Caesarean Section—Wallace has done a Caesarean section sixteen times the indication for interference being deformity of the pelvis in 13 cases and obstruction by tumors in three cases The 13 operations for pelvic deformity were performed on nine women, six of whom underwent section once, two twice, and one thrice In the three cases, in which tumors formed the obstacle to delivery, obstruction was offered by advanced carcinoma of the cervix of the uterus in one case, by a large intraligamentous fibroid in another, and by a dermoid cyst of the left ovary in a third Of the 16 operations, one resulted fatally to the mother, so that the maternal mortality was 6.25 per cent All the children were delivered alive, but one survived only a few hours The maternal fatality was due to sepsis, the result of several attempts at delivery before Caesarean section was done

27 Postpartum Hemorrhage—Tweedy subscribes to the efficiency pressure exerted on the abdominal aorta as a means of temporarily controlling postpartum hemorrhage

28 Embolism.—Hall discusses multiple embolic aneurisms and fatal pulmonary embolism, citing cases in illustration

29 Antiseptic Action of Metallic Sutures.—In the case of the majority of the metals tested by Leedham Green as to their antiseptic action, the presence of a wire loop in gelatin inoculated with the staphylococcus aureus seemed to have little or no influence on the growth of the micro organism. On the other hand, it was evident that some of the metals had a distinct and powerful inhibitory action on the growth of the germ. In these cases, the culture medium in the immediate neighborhood of the wire loop remained free from bacterial growth, thus forming a clear, transparent halo about the metal ring. Gold, platinum, tin, magnesium, nickel, lead, silver and aluminum were found to possess practically no inhibiting power. Iron exhibited a variable action, dependent on whether oxidation was favored or hindered. If no oxidation took place, then no inhibitory action could be detected, when there was free oxidation, the inhibitory action was decided. By far the most powerful of the metals, bactericidally, proved to be copper, and in a less degree (according to the percentage of copper used in their composition), its alloys, bronze and brass. Similar experiments were made with screws and nails, and the results were the same as in the case of the wire.

31 Methods of Treating Heart Disease.—In this, the third paper of the series, Bennett discusses the matter of diet, what to eat, how to eat, and how to prepare properly what we eat.

Dublin Journal of Medical Science March

- 33 *Treatment of Gastric Ulcer. J. Little.
- 34 *Treatment of Non malignant Gastric Ulcer. C. Ball.
- 35 *Gastric Ulcer. Its Diagnosis and Treatment. J. A. Lindsay.
- 36 *Treatment of Gastric Ulcer from Surgical Standpoint. A. B. Mitchell.

33 Treatment of Gastric Ulcer.—Little says that during his practice before gastric ulcer was made a disease for surgical intervention, all his knowledge of the appearances of gastric ulcers was gained by seeing them in cases which had become fatal from perforation. In other words, he can not recollect a case in which gastric ulcer ended fatally either by gradual exhaustion, or by hemorrhage. He says that with some exceptions the remedy for gastric ulcer is confinement to bed. Diet and medication are of some importance, but the kind will vary with the individual case. Little says that doubt as to the value of surgery in the treatment of bad stomachs has been somewhat suggested by the fact that of late years a few people have consulted him for stomachs which still gave them great trouble, and when noting the principal signs he found that there was a scar, five inches long, in the linea alba.

34 Treatment of Non Malignant Gastric Ulcer.—Ball urges that all cases of uncomplicated gastric ulcer which have had a reasonable trial of treatment by rest and limited diet without very marked improvement, should be subjected to gastroenterostomy. He prefers the posterior operation.

35 Gastric Ulcer.—Lindsay says that the physician should recognize that the intervention of surgery in the treatment of gastric ulcer has been of great value, and that he should be careful not to postpone too long his appeal for assistance to a surgical colleague. He should seek that assistance in most, if not all relapsing and chronic cases. On the other hand, the surgeon should recognize that his assistance is required only in a minority of such cases, that a full, and even patient trial of medical measures is always the first duty, and that he should be chary of mere exploratory operations.

36 Id.—In Mitchell's opinion, exploratory operation is an unscientific proceeding. He says that there should always be some definite diagnosis, and that operations should be undertaken with a deliberate object in view. It is wrong to open the abdomen, to see whether it ought to have been opened. He thinks that a properly performed gastrojejunostomy may

be relied on to cure 90 per cent of the patients, and that those in whom failures occur will be found to have some other ailment militating against success. He says that after a fair trial of medical treatment without satisfactory results, operation should be considered before the health of the sufferer is undermined and the stomach so deformed or adherent as to require some elaborate and dangerous surgical procedure.

37 Torsion of the Great Omentum.—Lejars reports what he thinks is the first case of volvulus of the great omentum diagnosed before operation. In the 66 cases on record, he says, the volvulus occurred in the majority with a right inguinal hernia, in others with an empty hernia or without hernia. His patient was a man of 37, sent to the hospital on a diagnosis of appendicitis at the eleventh day. He had had right inguinal hernia for 20 years, kept under control with a truss, and was suddenly seized with colic and diffuse pain throughout the abdomen, vomiting and slight rise in temperature. There was no constipation, and the pain finally settled in the right iliac fossa and flank. A large rounding mass could be palpated in the right half of the abdomen, extending from the crural arch to above the umbilicus. It was doughy, slightly nodular, no where fluctuating, and palpation was uniformly painful. Below, the tumor seemed to be connected with the contents of the hernia by a thick cord crepitating a little under the finger but not tender. There was dullness over the entire region occupied by the tumor and the hernia. By this time there were no reactions, no nausea, stool was apparently normal and temperature only slightly above normal. The connection between the hernia and the mass in the abdomen and the comparative mildness of the symptoms suggested the diagnosis of volvulus of the great omentum, which was confirmed by the operation. The part of the omentum involved in the hernia was twisted and again, close to the transverse colon, where the entire mass had twisted three times on its axis. The torsion at this point was readily corrected and the mass was cut away just above it. The appendix was adherent to the mass and was removed with it. The wound was sutured over two small drains and the patient rapidly recovered. A hernia offers favorable conditions for the development of volvulus of the omentum even if the hernia becomes spontaneously corrected in time, although seven cases are on record in which the torsion was entirely intra-abdominal with no tendency to hernia. This group includes Stewart's case published in THE JOURNAL, March 19 1901. The evolution of a volvulus of this kind is generally slow, and the reactions mild but nevertheless the condition is a grave one and may terminate in gangrene or complete detachment of the omentum from rupture of the twisted pedicle. In the 66 cases on record seven of the patients died. It is wise to operate at once when the condition is recognized as adhesions grow constantly more numerous and harder to detach. It is also wise to examine the omentum up to the transverse colon as there may be torsion at more than one point. In von Lejars' case the volvulus in the hernia was rectified but at autopsy it was found that the omentum was twisted at three other points above not suspected at the operation. He states that the entire "tumor" must be removed into sound tissue, even if it requires the ablation of the whole of the omentum.

38 Acute Dilatation of the Heart.—Cheinisse discusses whether or not it is possible for a sound heart in a healthy person to become suddenly dilated as a result of overexertion and then to subside rapidly again to normal. He reviews the recent literature on the subject of pharyngeal constriction and its effects on the heart as studied by

radioscopy, and concludes that the evidence is rather against the possibility of physical exertion producing acute dilatation of a sound heart in healthy individuals. On the other hand, the evidence shows that this is liable to occur in case of sudden emotional stress, especially in neurasthenics. Cheinisse has already demonstrated that emotional stress, intense anxiety, is able to induce the development of acute organic affections of the nervous system, and he thinks that somewhat the same mechanism explains the acute dilatation of the heart observed in apparently healthy individuals. Marmorstein reported last year two such cases caused by the rioting at Odessa. The patients were Jews, and the emotional shock at the spectacle of murder and pillage in their homes induced acute dilatation of the heart, which subsided after a few hours. Both of these patients had a history of neurasthenia. The cases resemble those related by Kress in which acute dilatation of the heart was observed in two neurasthenics in the course of transient psychic disturbances. The emotional stress acts on the vasomotor nerves, the arterial spasm inducing a hypertension which reacts on the myocardium. It is also possible that the moral shock has, further, a direct action on the centers regulating the innervation of the heart. The suddenness of the moral shock annuls the power of adaptation which protects the heart against physical over exertion under the circumstances.

39—See news item in THE JOURNAL for March 16, page 958

40 Unilateral Decapsulation of Kidney in Treatment of Eclampsia.—De Bovis adds another to the five cases of eclampsia of which he has knowledge in which Edebohls' technic of decapsulation of the kidney was applied. His patient was a frail young woman with traces of albuminuria when she entered the hospital in labor at term. Four hours after 10 hours of labor and normal delivery, eclamptic convulsions occurred and returned about every hour, with 17 spasms in all between 9 a. m. and 6 the next morning. At this time the patient was still unconscious and extremely restless, with incontinence of urine, pulse 90, the lungs slightly congested, the face moderately cyanotic. The operation of decapsulation according to Edebohls' technic was performed at 10 a. m. on one kidney, consciousness returned by 5 p. m. and recovery was soon complete. This is the first case of unilateral decapsulation in eclampsia on record. In this case and in two others there were no signs of "renal glaucoma" as the condition of extreme congestion and hypertrophy of the organ has been aptly called. The kidney was smaller than usual with a large ecchymosis on the convex side. There was not the least tendency to hemorrhage, so that the benefit could not have been due to loss of blood. The aim is to aid the functioning of the kidneys and an operation on one kidney alone might be sufficient, as in the case reported. De Bovis is inclined to believe that nephrotomy should be reserved for the cases with anuria or extreme oliguria. He cites Büttner's statistics, taken from the midwives' register in Mecklenburg, showing the mortality in 509 cases of eclampsia. During pregnancy, 4.5 per cent. of 22 cases, during labor 24.4 per cent. of 323 cases, and after delivery, 30.4 per cent. of 164 cases. These figures justify intervention, he thinks.

41 Eclampsia, Result of Arterial Hypertension.—Vaquez reviews the various theories in vogue in regard to the etiology of eclampsia and points out their fallacies. None of them, he says, has taken account of the main and essential feature of eclampsia, the arterial hypertension, which he regards as the essential symptom, testifying to vascular disturbances whose existence and importance have heretofore been disregarded. Lesions in the liver or kidneys are not constant, and when present, are the result of the disturbances which they are supposed to explain. The origin of the hypertensive vascular spasms which are the essence of the eclampsia, causing the convulsions and the modifications in the viscera, is still a mystery. The most plausible hypothesis ascribes it to some disturbance in the vascular glands the thyroid, suprarenals or chromophile glands which regulate the arterial pressure and which have such an important influence on the genital sphere in women (puberty, menstruation and menopause). During the last 10 years he has been studying the arterial pressure in

cases of eclampsia, and with the Basch Potain sphygmomanometer has always found it from 10 to 14 cm., mercury, higher than normal. When the sphygmomanometer reveals a great increase in the arterial tension the convulsions are not long in making their appearance. If the tension persists high, further trouble may be anticipated. The hypertension does not depend on the convulsions, but precedes them. In one case a woman had apparently recovered from puerperal eclampsia a month before, but intense headache and maniacal excitement persisted. The arterial tension remained high—23 cm.—and in a few days the patient died in delirium, after a few terminal convulsions. Another patient who had exhibited only symptoms of impending eclampsia, with persistent high arterial tension, succumbed three weeks later to sudden meningeal hemorrhage, complaining in the interim only of recurring headache. In cases with a favorable prognosis, the arterial tension rapidly subsides nearly or quite to normal, with a few transient rises at times. The patient may succumb after the arterial tension has returned to normal and all convulsions have long ceased, as the extremely high tension may have induced irreparable lesions at some point.

The practical conclusions of Vaquez' long article are that it is necessary to examine the blood pressure as systematically as the urine in case of threatening eclampsia, both for diagnosis and for prognosis. He affirms positively that eclamptic convulsions will never be encountered in women with normal arterial tension, while they may be apprehended whenever the arterial tension is found unusually and persistently high. There is no hypertension, he states, in physiologic pregnancy and parturition. Among the signs of hypertension are the accentuation of the second aortic sound and dilatation of the arch of the aorta. Percussion may also disclose dilatation of the left ventricle, and examination of autopsy records will show that hypertrophy of the left ventricle is frequently encountered in eclampsia. Both this and the dilatation of the aorta do not appear until the hypertension has lasted for some time, consequently they generally indicate, when found, that the hypertension has long preceded the vascular spasms and the eclampsia. In one case a woman had a pressure of 25 cm. when she entered the maternity and eclampsia was apprehended. Delivery occurred the next day, followed by eclampsia which soon terminated in fatal coma. Sometimes the high arterial tension is accompanied by amaurosis, tetany, mania or the like, without actual eclamptic spasms, although the tension may be at 25 or 27 cm. On the other hand, a tension of only 18 or 19 may coincide with true eclampsia, but it generally rapidly subsides in this case and the tension drops gradually to normal (13 or 15 cm.).

The modifications in the heart and vessels noted in impending or established eclampsia are not peculiar to this affection. They are encountered likewise in uremia, especially in the form with convulsions, and in lead colic even when there is no suspicion of kidney trouble. The modifications in the vascular system and heart are merely the expression—equally significant in eclampsia, convulsive uremia and lead colic—of the abnormally high arterial tension. Sudden and rapidly subsiding amaurosis, certain forms of tetany, the maniacal delirium of pregnancy and after parturition, and the cases of "eclampsia without convulsions," are all links in the chain of eclampsia, all depending on the arterial hypertension. In eclampsia these various manifestations may all be crowded into a few hours, while in uremia they may string along through months and years. There is no other affection, Vaquez adds, accompanied by such high arterial tension as eclampsia, and there is no other which is so habitually characterized by hemorrhagic phenomena.

Toxic or infectious processes have been supposed to be responsible for the hemorrhagic foci, but Vaquez thinks that they are explained much better by mere mechanical conditions. When the arterial pressure rises in a few days from 14 to 26 or 28 cm., actually doubling, the only cause for wonder is that the vessel walls do not rupture even more frequently. This is probably due to the fact that eclampsia generally occurs in young women with sound vessel walls, able to stand considerable strain. When rupture does occur, the

amount of blood that escapes is usually in proportion to the degree of arterial tension. What he calls "meningeal epistaxis" is extremely frequent in eclampsia, revealed by the presence of red corpuscles in the cerebrospinal fluid even when there is no copious hemorrhage in the membranes. Ménétrier has recently reported a case of lead poisoning with convulsions in which the blood pressure measured 27 cm, without a trace of organic lesions to be discovered at autopsy. Vaquez believes that nothing but mechanical conditions will explain the sudden onset of the kidney disturbances in eclampsia, their intensity and the rapid return to normal—this "eclipse of the kidneys," as he calls it. In one case reported, the urine contained 0.5 gm of albumin the first day, 62 gm the second, 37 gm the third, and 0.2 gm the fourth day, with a corresponding increase and decline in the proportion of acetone and bile pigments and normal conditions by the fourth day. Any individual who has had repeated attacks of arterial hypertension from vascular spasm is threatened with chronic hypertension in after years, as he shows by examples from his clinical experience.

42. Chemical Differences Between Human and Cow's Milk.—Biedert reviews the progress made since he presented an inaugural thesis on this subject 40 years ago, the first ever devoted to this theme, he believes. It was prepared under Kehrer's supervision and, among other points, emphasized the necessity for chemical examination of infants' stools as a guide to treatment. This will differentiate at once the cases in which the digestion of fats is defective from those in which fat digestion proceeds normally. The former require abstention from fat, while the latter thrive on it.

43. Abdominal Cesarean Section in Comparison with Other Operations for Contracted Pelvis.—Frank reports 13 cases in which he performed this operation. All the patients had been manually examined with little regard to asepsis before entering the maternity. The results of the operation were excellent in every instance. He regards delivery by the abdominal route as affording more favorable conditions for the mother than delivery by the natural passages later if accompanied by much trauma. This is particularly evident in already infected cases, as he shows by examples. Abdominal delivery he thinks is free from danger, comparatively speaking, and he believes it is destined to prove the standard procedure in cases of contracted pelvis. He recognizes certain indications for the pelvis enlarging operative measures, but adds that unforeseen mishaps are liable to occur, as he knows from personal experience. The degree of contraction of the pelvis is immaterial for Cesarean section, and febrile conditions are no contraindication. The operation is not able to cure infection in the uterus any more than other measures, but the child is saved, fatal septic peritonitis is avoided and better conditions are afforded for combating the uterine infection than by any other technique.

44. Physiology of Third Stage of Labor.—In Heils' experience with a series of 120 parturients the placenta was ready to be expelled within thirty minutes after the birth of the child. He tabulates the findings according as the uterus

was still contracted and like a ball, or as it had 'flattened out.' He concludes that it is not advisable to wait longer than half an hour for expression of the placenta in case of physiologic delivery and, in the interests of the rest requiring parturient, it is not desirable. He examines in from 10 to 15 minutes after delivery to see whether the uterus is still contracted into a ball or has flattened out. In case of the latter finding, it can safely be assumed that the placenta can be readily expressed at the end of the half hour. He regards this flattening of the uterus as a sign of the descent of the detached placenta into the passage below, and fully as reliable an indication as the lengthening of the umbilical cord.

46. Importance of Icterus During Pregnancy.—E. Kehrer adds another to the 11 cases on record in which catarrhal icterus developed during the course of a pregnancy. His patient had long suffered from occasional slight icterus, and it assumed serious proportions at about the sixth month of her first pregnancy. The case is distinguished by the prolonged catarrhal icterus, the severity of its manifestations and accompanying cutaneous hemorrhages, pruritus and diarrhea, by the hemorrhagic diathesis observed in the child—observed likewise in Frank's case—and by the signs of mild osteomalacia and cranial neuritis during the puerperium. The icterus vanished after delivery. In 2 other cases icterus coincided with uncontrollable vomiting, albuminuria and ptalism in pregnant young women. The icterus of pregnant women is a serious condition on account of the cholemic hemorrhages, the loss of sleep from the itching, the emaciation from lack of appetite and from diarrhea, the liability to periods of excitement and to infection from scratching the itching skin, and also the tendency to osteomalacia and neuritis from the elements of the bile circulating so long in the blood. But the condition is still more dangerous for the child in some cases. Premature delivery occurred in 26 out of the 30 childbirths of 8 women with this icterus during pregnancy. In only 2 cases did delivery occur at term, and only 11 of the 31 children were born alive. In another group of 7 cases of catarrhal icterus, cholecystitis or cholangitis, only 4 of the children were born alive and one was scarcely viable. Lomer collected from the literature 57 cases of catarrhal icterus plus acute yellow atrophy of the liver in pregnant women, and the intrauterine death of the fetus was noted in 45 cases. Kehrer regards it as strange that pediatricists writing of the hemorrhagic diathesis in children never mention whether or not the mothers had icterus during the pregnancy. In 28 cases the child of a mother with icterus and acute yellow atrophy of the liver presented no signs of icterus, while in 7 other cases congenital icterus was observed also in the child. Experimental research is further related which shows that the healthy placenta in laboratory animals does not allow the passage of the elements of the bile to the fetus but responds with extreme hyperemia to the intoxication of the maternal organism. In treatment the usual measures for icterus are advised if the condition does not last more than two or three weeks. If it persists longer than this or increases in intensity, it is much better to induce delivery and to rear the child in an incubator with a wet nurse than expose it to the almost certain danger of the hemorrhagic diathesis or icterus, as every day new amounts of the elements of the bile are being poured into it, poisoning its blood more and more. As the bile acids pass into the milk of women with icterus, it is best to substitute the milk of some other woman even when the children are born apparently sound. Some substance that will neutralize the bile salts in the maternal blood may yet be discovered but, he states, none is known as yet.

52 Differentiation of Pus of Various Origins by Proteolytic Ferment Action—This article describes further applications in the clinic of the Müller Joellmann test for differentiation of pus by the proteolytic action of the ferments. The test is proving extremely reliable, the high temperature insuring the sterilization of the material and hastening the action of the ferment. A few drops of the pus to be examined are placed on the smooth surface of a Loeffler plate, that is, a Petri dish containing a rather thick layer of hardened beef or sheep serum. The plate is then placed for 24 hours in an incubator at 122 or 131 F. In case the pus contains a proteolytic ferment, each droplet digests the serum below it and the result is a little hollow at the point of contact. In case there is no proteolytic ferment present, the droplets merely dry on top of the serum with no tendency to hollow it out. This is what is always observed in case of pus from pure tuberculous processes. More than 100 tests with pus from carbuncles, acute gonorrhea, appendicitis and dozens of other affections, all induced by cocci or colon bacilli, invariably showed pronounced proteolytic digestion and consequent dimpling of the hard serum on the Loeffler plate. The lack of evidences of pronounced proteolytic ferment action is therefore a sign of a pure tuberculous process. The presence of the proteolytic action, however, does not exclude tuberculosis, as there may be mixed infection or the findings may be disturbed by preceding iodoform treatment, or by admixture of fresh blood.

60 Epidemic Cerebrospinal Meningitis—Knauth reviews the experiences of the last thirty years in the Bavarian army in regard to epidemic cerebrospinal meningitis. He ascribes it to various causal agents in different epidemics, the pneumococcus cases being apparently the least serious, although commencing with an unusually stormy onset.

62 Metastases of Hypernephroma—Hoffmann reports 2 cases in which a hypernephroma had developed in the kidney without attracting attention. The patients applied to a physician only when metastatic affections in the bones or elsewhere were observed. In the few, similar cases on record the bone affection was assumed to be primary and was treated as such. In Israel's case two small lumps in the ribs were the first signs of trouble. Albrecht has also reported 4 cases out of 28 of hypernephroma in which a tumor in the bone was the first lesion noted. In these cases, the tumor was removed on the diagnosis of myelogenic sarcoma or tuberculous osteoperiostitis. With Hoffmann's first patient, pruns in the legs and shoulders were the first symptoms, explained by small tumors discovered at the autopsy with numerous other metastases in the spleen, pleura and elsewhere. In the second case, a tumor at the entrance of the urethra, another in the vagina and a third on the inner surface of the thigh were found at the first examination, and the structure of the latter tumor was found to be similar to that of a hypernephroma. These experiences suggest the importance of bearing the possibility of hypernephroma in mind when consulted on account of a tumor, especially a tumor in the bone by a patient past 50 even when no local or remote symptom points to a kidney tumor.

63 Treatment of Hemorrhoids—Franck applies a polyp snare to the nodule, under local anesthesia, and slowly tightens the wire loop around the base of the nodule until it becomes extremely congested. Holding the loop tight in the

left hand, he injects with the other hand from one fifth to one-third of the contents of a Pravaz syringe filled with 60 per cent carbolyzed alcohol. In from 5 to 10 minutes the nodule has hardened completely under the influence of the injection and the constricting loop is then loosened, and the next nodule attacked. He advocates this technic for all chronically inflamed or bleeding hemorrhoids when there is any hesitation about applying general anesthesia. Deep fissures are the only contraindication, they require cauterization. The use of the polyp snare renders the operation much simpler and easier than when a silk ligature is used.

65 Alimentary Intoxication in Infants.—Finkelstein relates his experiences in years of research on this subject, with special regard to the collapse, disturbances in consciousness, peculiar change in the rhythm of respiration, alimentary glycosuria, fever, diarrhea, albumin and tube casts in the urine, abrupt decline in weight and leucocytosis. The presence of these nine factors in the clinical picture is indispensable for the conception of what he entitles "alimentary" intoxication. The leucocytosis approaches but seldom reaches 30,000. The respiration is deeper and faster, and the gestures, instead of the "angular," rapid movements of health, become rare, languid and "rounded," the corners of the mouth are drawn down, the arms and legs take unusual positions, sometimes stretched out, sometimes drawn up, relaxed or rigid. The lower blood pressure brings a livid tone to the complexion, with shadows around the eyes. It is important to see the child at rest to detect this intoxication in its incipency, when the child is aroused these signs alter. The stools may be approximately normal even with these symptoms of serious intoxication. The sugar in the urine and the deep breathing differentiate this intoxication from the numerous infectious diseases which may be accompanied by some of the other signs. He suggests that these two signs may also prove useful for differentiating in adults brain affections from disturbances due to autointoxication, such as acetoneuria and dyspeptic coma. In infants the appearance of the pathognomonic symptom complex is an indication that a new specific process is going on in the organism. It is liable to be followed by specific, profound modifications of the metabolism. All the functions suffer, as he relates in detail. The intoxication is the expression of a regular reaction of the organism which always occurs when injury from any cause, such as an infectious affection or process or any deleterious influence, reaches a certain intensity. The intoxication is not the work of bacterial toxins, but of metabolic toxins, a sharp distinction should be made between them in this respect. Research is needed on the nature of the substances inducing the intoxication. The conditions are somewhat similar to those observed in uremia.

66 Later Development of Children Who Have Had Convulsions During Infancy—Thiemich and Birk have traced the later history of 64 children known to have had convulsions in infancy. The only similar work which they have found in the literature was Bullard and Townsend's article in 1901, and this does not distinguish between the various kinds of convulsions but lists all that are not true epilepsy. By "eclampsia infantum" Thiemich understands epileptiform convulsions of the entire musculature, sometimes occurring in series but lasting only a few minutes each time with loss of consciousness, and, during the intervals, marked signs of "spasmophilia," such as tetanic larvngospasm, with the Trou-

seau or facial sign, or morbidly increased electric excitability. In the 64 cases reported, the onset of the eclampsia always followed metabolic disturbances. Only 2 of the children were even partially breast fed. Dietetic measures were the main reliance in treatment, supplemented usually by phosphorus cod liver oil. In 37 per cent heredity was an unmistakable factor in the convulsions, and in 13 per cent there was neuropathic heredity—a total of 54 per cent of proven heredity. No instance of epilepsy was found in the parents or family of any of the children. Two thirds of the children were found later to be below the average of intelligence or morals, and some of the others are only children. The writers add that the fact of being an only child, as is well known, affords a predisposition for nervous affections. An only child sometimes is helped at home with his studies, thus enabling him to be rated as normal at school—to the child's great disadvantage, as he succumbs sooner or later to the mental strain. Many an early maturing only child, who ranked high in his early school life, falls far below the average later, if he does not end as a "psychopath." The later development of the children with laryngospasm alone did not differ in any respect from that of the children with pronounced eclampsia. Only a very small percentage of the eclamptic infants developed into normal children.

68 Operative Treatment of Diphtherial Stenosis of the Larynx in Infants.—Molschanow reviews the experience at Moscow with intubation in laryngeal stenosis from diphtheria. Out of a total of 193 intubated children, 21 were less than a year old. Ten of the infants recovered.

70 Tuberculosis of the Flat Bones of the Skull.—Reber reports 24 cases in children. None was under a year old, but 12 were between 1 and 2, and 11 between 2 and 10. In 134 cases recorded in the literature, the age is mentioned in 105, and 46 of the patients were between 10 and 20, 37 between 20 and 30, only 9 under the age of 2, while 5 were between 30 and 40, and 5 between 40 and 60. In his own experience with 24 cases, 11 of the patients were clinically cured in a comparatively short time, recent reports from 9 show that the cure was permanent, and also that concurrent tuberculous lesions elsewhere were also permanently cured at the same time. In 5 cases large depressions were left in the bones, but in one case regeneration of the bone was complete. The mild cases healed without local treatment. Others required puncture and injection of iodoform emulsion or scraping and resection far into sound tissue. Multiple tuberculous foci were found in all the cases that terminated fatally, and in 61 of the cases on record.

71 Obstipation Due to Kinking of Intestine.—Pfisterer was able to differentiate and to relieve this condition in a boy of 6. In an infant the presumptive diagnosis was confirmed by the postmortem findings. In the other case, the sigmoid flexure must have been unduly long, as whenever the child was allowed to go a day or so without a movement of the bowels, signs of complete occlusion rapidly developed, which yielded, however, to castor oil and copious rectal injections. As the intestine straightened out, the child experienced sudden sharp pain, after which the stools passed readily. The parents were instructed to supervise the child's intestinal functions and thus put an end to further trouble. The anatomic conditions in early childhood favor this kinking of the intestine, and any disturbance in the digestive organs is liable to cause trouble from this source. The sigmoid flexure in children kinks easily, and the space in the pelvis, especially in boys, is contracted in comparison to the conditions in the adult. Rectal examination is important for differentiation, also the fact that large amounts of fluid can be introduced without its flowing out again. Fluid passes readily upward, but the valve-like closure of the kinked intestine prevents its escape. Pfisterer is convinced that a large proportion of the cases published as Hirschsprung's disease were, in reality, merely the result of this kinking of the intestine, generally at the sigmoid flexure, or the result of some primary or secondary anomaly in the mesentery. The assumption of a congenital deformity is sustained by the finding of other congenital malformations elsewhere.

72 Tonsils in Etiology of Appendicitis.—Kretz presents arguments to sustain the assumption that an acute angina may lead to bacteremia and the bacteremia to phlegmonous appendicitis. During the last 5 years appendicitis was the cause of death in 53 out of the 3,579 autopsies at the Vienna Franz-Josef Hospital. In only 14 cases was the autopsy complete, but in each of these there were evidences of recent tonsillitis. His experience in the clinic also favors the assumption of a connection between tonsillitis and appendicitis. The trouble is almost invariably the work of streptococci. From their primary invasion of the tonsils with resulting bacteremia, may result appendicitis, osteomyelitis, endocarditis, pleurisy, meningitis or myositis. Physicians in general fail to realize the connection between these affections, Kretz remarks, but they belong in a single group not only because they are the work of a certain pyogenic microorganism, but because they are connected epidemiologically by the common link "angina."

73 Gas in the Urine.—Adrian and Hamm devote this communication to the study of spontaneous gas formation in the bladder exclusively the work of gas producing bacteria. Three such cases have been published and they have had 4 similar ones under observation for some time. The patients were 4 men and 3 women between 23 and 66. Two of the women were pregnant. There was no glycosuria in any instance. Cystitis was present in every case. In 4 cases the colon bacillus was found in pure cultures, in 3 the *Bacterium lactis aerogenes*, once associated with cocci. The prognosis is dubious, especially for elderly persons. Experience with 2 of the cases suggests the probability of some serious affection of adjacent organs (cancer), favoring the development of the pneumaturia. The production of gas is probably due to bacterial decomposition of the albumin in the cystitic urine. Treatment can be only symptomatic, they say, as no efficient measures against bacterial pneumaturia are known.

74 Behavior of Remainder of Kidney After Resection.—Haberer reports experiments on 3 goats and 38 dogs in which resections of the kidneys were made as extensive as possible and at as brief intervals as possible, with implantation of fresh kidney tissue when more of the kidney had been resected than was compatible with life. His research is described in detail with illustrations. He was surprised to find that no less than 9 of the supposedly healthy dogs presented pathologic changes in the kidneys at the first operation. Among other facts learned is that some animals are able to survive two resecting operations on the remaining kidney after nephrectomy, even when all 3 operations are performed within from 25 to 34 days. The death rate, however, is very high for this series of experiments. At the same time they show that it is possible for dogs to survive extirpation of one kidney and reduction of the size of the other kidney to two thirds its size, all within a week, or reduction to one half its size by two operations following the nephrectomy within a month. The experiments further demonstrate that mild bilateral pathologic changes are liable to retrograde completely in the remaining kidney after a nephrectomy. Whether or not resection of the remaining kidney will be tolerated can not be foretold, even with crescospir and the phloridzin test. The latter proved an excellent index of the functional capacity of the renal parenchyma present. Whether general or the in

can affect the findings of the phloridzin test is still undecided. Repetition of the phloridzin test within brief intervals does not seem to influence the findings, but this test never reveals an anatomic lesion until it has induced functional disturbance. It is even possible that causes outside the kidney may entail functional disturbances revealed by the phloridzin test. It was astonishing in the experiments related to note the almost complete absence of even transient general disturbances from removal of one kidney.

77 Diagnosis and Treatment of Occlusion of Arteries in Gangrene of the Foot—The application of a tourniquet for 5 minutes with the consecutive active hyperemia as the blood rushes back into the parts has proved a valuable means of determining the conditions of the blood vessels in the region. With sound blood vessels the region becomes red and warm, while with occluded vessels the pallor persists or the skin only slowly returns to normal tint. Moszkowicz's experiments on the cadaver and in the clinic demonstrated that the occlusion of the artery was always localized by the stoppage of the return flow of blood at this point or just above. Further clinical experience is necessary to determine whether amputation can be done at this point or whether it is wiser to leave more space and to amputate a few inches above the point where the active hyperemia is arrested. Another important question yet to be decided is whether or not it might be wiser to take the flap on the side where the hyperemia extends farther downward. He first raises the leg to expel the blood, then applies energetic constriction with an elastic band, as high as possible on the limb, and leaves the tourniquet in place for five minutes. On removal of the band the circulation is rapidly restored throughout the limb, even in case of arteriosclerosis, if the blood vessels are permeable. When the circulation is seen to be sufficient all through the leg except at the toes, expectant treatment is indicated, allowing the toes to drop off as in case of gangrene from freezing, or the whole or part of the foot can be amputated. But if the circulation is seen to be arrested above, the leg should be amputated without delay, above the point where the active hyperemia is arrested. If amputation is refused, by repeating the test the course of the case can be supervised and the development of occlusion from thrombi higher up can be determined. The patients can see for themselves the results of the test, and it much simplifies matters. Even with mere narrowing of the arteries, as in case of intermittent claudication, the active hyperemia test gives very instructive findings. It will differentiate the true cause in many conditions at present erroneously attributed to joint affections, flat foot, varices or hysteria. In conclusion, Moszkowicz suggests that possibly by repetition of this procedure of induced active hyperemia, the lumen of the vessels might become enlarged or the development of collateral circulation be promoted. Other measures to induce active hyperemia, including cupping apparatus, might also be tried although great caution is necessary, especially with superheated air.

SOME GENERAL PRINCIPLES IN CONNECTION WITH PROTOZOA AS FACTORS IN DISEASE *

CHARLES WARDELL STILES, PH D, D Sc

Chief of Division of Zoology U S Public Health and Marine-Hospital Service
WASHINGTON, D C

At the risk of repeating statements already well known, I propose to discuss certain general principles concerning protozoa especially in connection with disease. Such a discussion is not entirely free from the risk of laying myself open to attack, but I believe that it is a good plan to return occasionally not only to general principles but also to elementary facts. If such a discussion provokes adverse criticism, either in public or in private, the criticism itself may accomplish some good and thus justify this paper.

We have heard a great deal during recent years about protozoa in relation to disease, and during the next twenty years we shall hear much more, for, quite aside from studying these animals as a cause of disease, we can, I believe, conservatively hope to find in their study valuable clues to solutions of many obscure problems in cytology of higher animals. This phase of protozoology is capable of playing as important a rôle in medicine as the subject of pathogenic protozoa is now playing in pathology, and I am fully persuaded that eventual practical results would more than justify the establishment of several university chairs of protozoology, with the distinct understanding that the incumbents should devote a not inconsiderable amount of their time to a purely abstract and academic study, without even permitting the question of the immediate practical application of their conclusions to arise in their minds. I believe thoroughly in applied protozoology, but I look for equally important ultimate results in academic protozoology, and I hope that the very just and perfectly natural utilitarian tendencies of our times will not inhibit the obtaining of further fundamental, but at present academic, principles which this group of animals seems to offer.

Now if protozoa are of such importance, both academically and practically, as they seem to be, let us ask the question: From our present standpoint of knowledge what are protozoa? This question may seem absurdly elementary, for we are prone to consider that the conception of such a common word as "protozoa" is thoroughly established.

For myself I am free to confess that the more I read and study on protozoa the less clearly am I able to form

a systematic conception of what really are protozoa and what really are not protozoa. I will go even further and lay myself open to attack by making what may seem to physicians to be an unscientific admission, namely that, while in numerous instances I feel capable of reasoning out that certain organisms are or are not protozoa in numerous other cases I feel as much confidence in a conclusion based on my intuition as in a conclusion based on my reasoning. Fifteen years ago I would not have wished to make this admission but the more experienced one becomes the less fear he has of admitting his ignorance, the limitations of his ability and above all the important fact that it is very difficult, often impossible, to draw sharp boundaries in Nature.

Let us turn for a moment to the systematic conception of the protozoa.

Most of us would probably not object very strenuously to defining the protozoa briefly as unicellular animals. As a general proposition this definition is more or less acceptable to me, with however, the important mental reservation that zoologists the men who spend their lives studying animals, are unable to give a definite concise uncriticisable definition of an animal and, further, that the term unicellular as applied to the protozoa is not absolutely free from criticism.

As a matter of curiosity, I have recently examined a number of standard books to see how various authors attempt to describe the protozoa systematically. The study was interesting, but the results could be more or less clearly foreseen.

Several prominent authors speak of the protozoa in a way which might leave the unguarded reader under the impression that these organisms represent a distinctly defined group of animals. Prominent among the characters attributed to the group are the following:

- 1 A unicellular structure with one or several nuclei
- 2 If several cells unite to form a colony these cells still preserve their independent nature
- 3 Tissues and organs are absent in the sense that tissues are structures composed of similar cells similarly united and organs are combinations of tissues for specific functions but a quasi tissue differentiation is more or less admitted for the protozoa and organelle are distinctly admitted
- 4 The usually microscopic size with numerous exceptions
- 5 Simplicity of structure the word simplicity being more or less qualified
- 6 Non sexual reproduction by division budding and spore formation and often sexual reproduction
- 7 Habitat in water or in a moist medium

It is no secret to zoologists that these characters singly or in combination are not sufficient to enable us to determine definitely in all cases whether a given organism is or is not a protozoan and we should recall that when authors speak of the protozoa in the manner indicated they are doing so with more or less political license in order not to plunge themselves into uncertainty and confusion.

* Introductory address in a Symposium held before Section K, American Association for the Advancement of Science New York, Dec. 27 1906.

Turning from the class of works just referred to, and consulting the more philosophical and less didactic essays, the fact stands out very prominently that certain authors (Cobbold,¹ 1879, Doflein,² 1903, Leuckart,³ 1879, Ward,⁴ 1894) frankly admit their utter inability to give a concise and definite systematic definition of protozoa while many other authors avoid the question by omitting a definition and confining their remarks to a general discussion.

There is nothing new or startling in what has just been said. These facts are known to every professional zoologist and to many physicians. But I have a distinct object in bringing this matter to your attention to-day, namely. In our numerous discussions as to whether the causative agent of this or that disease is an animal or a plant parasite, let us recall that zoologists may have a legitimate difference of opinion on certain cases, because of the fact that in the present state of zoological knowledge cases may come to our attention in connection with which it is impossible for us to eliminate completely the subjective element and to give an absolutely objective opinion. If now conditions are such that professional zoologists may hold different opinions on a given case, without any implication that we are unreasonable or in our dotage, is it strange that physicians and pathologists, to whom zoology is a side issue, should differ in their interpretations?

To my mind, the natural conclusion is that two men may differ in opinion as to whether *Treponema*, *Plasmodiophora*, *Cercomonas*, *Lambia*, etc., are animals or plants, and yet they do not thereby forfeit all rights to retain their systematic position as members of the species *Homo sapiens*. Let us expect in the future to meet wide differences of opinion in such cases, and let us accept these differences as having a certain amount of fundamental right to existence.

Admitting, now, the inability of zoology to concisely define the *Protozoa*, let us glance for a moment at certain conclusions which authors have reached regarding systematic limits of certain groups of *Protozoa*.

Several years ago zoology had a satisfactory classification for the *Protozoa*. We recognized the *Ciliata*, the *Flagellata*, the *Sporozoa*, the *Rhizopoda*, etc. To-day the limits and relations of these groups are by no means so distinct as formerly supposed. Some eminent botanists claim the flagellates, and two of the most prominent zoologists were, until they died a few years ago, firm believers in the view that the zoologists had as much right to the bacteria as did the botanists. In view of the recent results in the flagellates and sporozoa, showing that in neither group is the organization so simple as was formerly supposed, the limits of these two groups—once assumed to be so sharply defined—are now more or less confused and I doubt whether even Calkins, whom I view not only as one of our leading living American authorities on protozoa, but also as one of the foremost protozoologists America has ever produced, would care to go under oath as to whether certain forms are flagellates or sporozoa.

The second point which I wish to make, therefore, is that for some years to come we must expect to meet with a considerable legitimate difference of opinion

among authors as to the exact systematic position of certain organisms, even when it may be generally admitted that they are protozoal rather than protophytic.

In what do these confusing conditions find their natural explanation? To my mind, the explanation is, to no little extent, historical. Up to a few years ago, or, at most, a few decades ago, the protozoa were very interesting little creatures which a zoologist felt justified in studying provided he had nothing better on hand, or provided he became especially interested in them academically and was fortunate enough to be in a position to study them. Under these circumstances, it is not strange that the classification used to-day is not altogether satisfactory. Then the technic improved, and our friends, the pathologists, began to discover zoological principles which the zoologists had overlooked, and now zoologists are being forced to a more careful study of the protozoa. Let us not forget that we owe the impetus for this study chiefly to medical men like Lœsch, Laveran, Theobald Smith, MacCallum, Councilman and others. Had these men never pointed out the practical importance of the protozoa, it seems an open question whether zoology could now boast of a Thelohan, a Mesnil, a Nuttall, a Schaudinn or a Grassi as eminent students of protozoa. This statement is made, of course, without any reflection on the greatness of Balbiani, Buetschli, Stein, Schneider and other recognized protozoologists who have studied the subject chiefly from more academic points of view.

Again, in studying any animal, the biology of which is not known to us, we naturally and very properly try to foresee theoretically what the life history probably will be. In this we reason on analogy. Such reasoning is thoroughly justified and is frequently confirmed by practical study. In this speculative forecast, our reasoning is based chiefly on known facts and known principles rather than on facts and principles as yet unrecognized. Further, terms are used with the conceptions attached to them at the time the forecast is made. These theoretical forecasts are subject, however, to two important modifications as time goes on, namely. First, to a change in the conception of systematic units, due to additional knowledge of taxonomic nature, and, second, to additional facts of a more strictly biologic character.

To take a specific example. Calkins has published a speculative life cycle for the alleged parasite of smallpox. There are certain points in his speculative cycle which have support in analogy, hence they are easily grasped, other points seem to be rather contrary to analogy. The fact, however, that you or I may have our misgivings as to whether the alleged parasite of smallpox may not possibly be the product of a parasite rather than the parasite itself, and the fact that certain points advanced are difficult for us to grasp should not blind us to the possibility that, after all, the real fundamental difference between those who support the theory of a smallpox parasite, and those of us who have our misgivings regarding it, may perhaps simply be that the former are from 5 to 25 years ahead of us in taxonomic and biologic conceptions. By no means has the last word been said on the possible protozoan etiology of smallpox. The existence of a difference of opinion at present, however, is not unjustified, on the contrary, it is fortunate for this very difference of opinion is bound to be one of the most important factors in bringing out the truth, further, it has its basis in truth, namely, in the fact that our present knowledge of the protozoa is so incomplete that such differences are inevitable.

4 Ward. Henry B. Protozoa. Woods' Ref. Handbook of Medicine and Science, August, 1904. vol. VIII. pp. 527-549.

Considering now the *Protozoa* as an ill-defined group of unicellular animal or animal-like organisms, and admitting the present complexity and confusion of the subject, let us turn to certain general rules in reference to their relation to certain diseases

In May, 1901, in harmony with the trend of the thought of that year, I formulated two general rules with reference to parasites and disease. My original formulation was as follows

We may lay down two general biologic rules, which, I believe, are enunciated to night for the first time. The first rule, to which at present a few exceptions are known, is that diseases which are accidentally spread by insects are caused by parasitic plants, particularly by bacteria. The second, to which no exceptions are as yet known, is that those diseases which are dependent on insects or other arthropods for their dissemination and transmission are caused by parasitic animals, particularly by sporozoa and worms

The difference between the accidental (or, better, the facultative) carrier and the obligatory carrier may be well brought out if we call the first method of dissemination a mechanical transmission and the second method a biologic transmission. The first does not assume or imply that the transmitted germ necessarily undergoes any evolutionary stages in the arthropod (as, for instance, in the case of the bacillus of typhoid, or the egg of an ascaris or of a tenia in or on the house-fly) while the second does imply that the intermediate host is necessary for the normal completion of the life cycle of the organism in question (as, for instance, the mosquito for the malaria parasite, or certain insects for certain tapeworms, nematodes and thorn-headed worms)

Novy and Knapp,⁵ in their superb paper on *Spirillum obermeieri*, state that

Hitherto it has been assumed that insect transmission indicates a protozoal organism, and in so far as the spirochetes are concerned, the chief evidence which can be now adduced in support of their animal nature is the fact of such transmission in the case of *Spirillum duttoni* and *Spirillum gallinarum*. The persistence of the spirochetes in such insects for months, and the infection of their eggs constitute the remaining argument in support of this view

This passage has produced, in the minds of several persons with whom I have discussed it, the impression that the biologic rules just quoted have been overthrown

I would point out, however, that the hereditary transmission of a germ, by the female through the egg to her young, can not be accepted as an argument for the protozoan nature of a given organism, for unless certain published (1904) observations are shown to be erroneously interpreted, plant parasites can be transmitted in this manner

Further, it should be noticed that Novy and Knapp immediately add (contrary to the conclusions of Dutton and Todd,⁶ 1905)

There is as yet absolutely no evidence that the spirochetes (i. e., spirilla from their point of view) actually multiply in these insects, much less any indication of the existence of a life cycle in any way comparable to that of the malarial organism

This last sentence is of great importance, for until it is shown that *Spirillum duttoni* and *Spirillum gallinarum* do undergo some necessary biologic changes in ticks it remains undemonstrated that the diseases caused by these germs are dependent biologically on ticks, and,

if not dependent on ticks for their transmission, then the ticks are mechanical, not biologic, transmitters

Certain forms of trypanosomiasis, for the sake of argument, may be admitted as commonly transmitted by certain insects, in certain forms of trypanosomiasis (as surra) it is not only theoretically conceivable, but the point is even claimed by some authors that birds can carry the disease, it is also perfectly reasonable theoretically, and this point appears to be well supported by published facts, that surra can be transmitted through wounds obtained in eating surra animals, it seems also theoretically possible that surra, like dourine, might be transmitted accidentally by coitus. All these possibilities go to show that surra is not yet proved to be biologically dependent on insects for its transmission, and this disease, though caused by an organism which is usually recognized as a protozoon, can not therefore, be legitimately cited as disproving the biologic rules quoted. The possibilities of transmitting malaria by birds, by ingestion, and by coitus, is unknown and undreamed of, so far as we know or can reason, the life cycle of the malarial organism, hence also the existence of the disease in nature, like the life cycle of infection with *Dipylidium caninum*, *Filaria bancrofti*, *Gigantorhynchus gigas*, etc., are absolutely dependent on insects, hence malaria comes within the second biologic rule

Are African tick fever and Rocky Mountain spotted fever of man and spirillosis of chickens valid exceptions to the second rule?

At present we can hardly argue conclusively on Rocky Mountain spotted fever in this respect, but it is to be hoped that the brilliant results obtained by Ricketts⁷ and by King this past year will be continued next year and give us further definite facts as to whether the transmission by ticks in that case is mechanical or biologic, and it is also to be hoped that they may be able to succeed, where I failed, in definitely finding a culpable parasite

As for African tick fever of man and American spirillosis of chickens, I am more than impressed with the brilliant work by Novy and Knapp, in which they argue that the parasites are plants rather than animals. At the same time, as they themselves emphasize, no necessary biologic stages of these parasites have been found in the ticks, hence I must submit that the possibility is as yet by no means excluded that these two diseases are not dependent on the ticks for their transmission. Who can say to-day that these diseases may not, like surra, be wound diseases, namely, transmissible through a wound made by almost any method which would at the same time contaminate the wound with infected blood? I am not yet, therefore in a position to admit that an exception has been proved to the second biologic rule, and much less am I in a position to admit that the rule has been overthrown. I would not of course go to the extreme of claiming that no exceptions will ever be known, for our conceptions of animals and plants may change and our knowledge of the protophytes is not yet complete. I do maintain however that the second rule holds to day as well as it did in 1901 for no exception has yet been proved

In connection with the interesting experiments of Dutton and Todd⁶ it is pertinent to call attention to the fact that while they have definitely proved certain points other points brought out although indirectly of certain interpretations call for further study under

⁵ Novy and Knapp. Studies on *Spirillum obermeieri* and Related Organisms Jour Infect Diseases Mar 1906 vol III pp 291-303

⁶ Dutton and Todd. The Nature of Human Tick Fever. Liver pool School of Tropical Medicine, Memoir 17 1905 pp 91-

⁷ Ricketts. THE JOURNAL A. M. A. Vol 4 1906 p 5 Oct. C 1 1906

complicating conditions than those which they describe. On analyzing their experiments, it seems to me that they have established the following points

1 In tick fever a certain blood parasite is found which they interpret as probably identical with *Spirochaeta obermeieri* [But which has since been described by Novy and Knapp⁸ as a distinct form, *Spirillum duttoni*]

2 This parasite and this disease can be transmitted by inoculating blood from diseased animals into susceptible healthy animals

3 This parasite and the disease can be transmitted to healthy susceptible animals by allowing the latter to be bitten by ticks collected from native houses, but not fed experimentally on diseased animals, accordingly, in Nature ticks can transmit the disease

4 Ticks caught in native houses (but apparently not tested for infectivity), when fed on sick animals which had been experimentally inoculated with infected blood, were able six days later to transmit the disease to healthy susceptible animals

[In this case it is not proved whether the infectivity of the tick dated from their feeding on the sick animal or whether they were infective when first caught, hence, a definite period of incubation in the tick can not be assumed from this experiment]

5 Five days after animals have been inoculated by tick bite the parasites may be found in the blood

6 Infectious ticks, collected in native houses, may remain infectious for at least 20 days after being collected

7 An experiment to transmit the disease through unbroken skin, by placing on it blood containing parasites, was negative

8 Dust and dirt from cages containing infected ticks did not transmit the disease through the abraded skin (Observations covered 14 days. Experiments with blood on the abraded skin do not appear to have been made)

9 So far as can be judged from the data published, tick fever can be hereditary in the tick from mother to young [This does not however, necessarily imply either a biologic cycle of the parasite or its animal nature]

The following points seem to me to be indicated, but not proved yet, further study and experiments in these lines are necessary

1 That tick fever can be acquired as a "wound disease," namely, by bringing infective blood into contact with abraded skin (Dutton's infection)

2 That an infectious tick is not necessarily infectious at all times (If infective only at intervals, this point would seem to support the contention that the parasite is protophytic rather than protozoal)

Whatever any later experiments may show, and without prejudice to such results, the following points do not seem to me to have been established as yet

1 That there is any minimum period of incubation in a tick experimentally inoculated before this tick is able to transmit the disease

2 That there is any necessary portion of a definite life cycle dependent on a passage of the parasite through the tick, hence this disease has not been demonstrated as biologically dependent on the tick.

Finally, it may be remarked

1 The maximum period of incubation in mammals is not yet established, hence great conservatism must govern the interpretation of certain of the experiments

2 The maximum period of infectivity of ticks is not yet established.

3 No experiments seem to have been made to determine whether or not infection may take place through food soiled by feces from infected animals

Summarizing, without prejudice to results any later experiments may show, the point is not yet established that tick fever, though transmissible by ticks, is biologically dependent on ticks for its transmission

In connection with the spirillois of chickens,

Marchoux and Salimbeni⁸ have shown that this disease can be transmitted by ticks (*Argas miniatus*), but they have also shown that it is transmissible through ingestion of fresh feces, for their experiment animal No 8, which was fed on fresh dejecta of a sick fowl, took the disease in 5 days. This latter experiment goes to show that the parasite in question (*Spirillum gallinarum*) is not dependent biologically on *Argas miniatus* for its life cycle, hence that it does not form an exception to the second rule under consideration

In regard to a possible necessary period of incubation in the tick, the only reference I have been able to find is a statement by Marchoux and Simond⁹ that

Argas miniatus, intermediate host of the spirillum of fowls, infects itself, like *Stegomyia fasciata*, by biting a sick individual *Argas miniatus* (like the *stegomyia*) does not manifest infectious power until after a lapse of a definite time

The premises of this conclusion are unknown to me, hence I can not judge it fairly, but nowhere in the literature have I as yet been able to find experiments which support it. Whatever the premises may be, the fact remains that, according to published experiments, the disease is also transmissible through the feces

Turning now to yellow fever. In May, 1901, shortly after Reed, Carroll, and Agramonte published their epoch-making experiments, I said in the address from which I quoted above

The fact that yellow fever is transmitted by the bite of the mosquito not until a considerable time—namely, 12 days after the insect has sucked blood—indicates very strongly that yellow fever is caused, not by a bacterium, but by a sporozoön (I was, of course, using the term sporozoön in its 1901 conception). If this latter supposition can be demonstrated, then the conclusion will from analogy, be warranted that mosquitoes, and probably only mosquitoes, can transmit this disease. If, on the other hand, the disease should be proved to be bacterial in nature, analogy would not at present (in 1901) warrant us in concluding that mosquitoes are either necessary to its transmission or that they are the only transmitters

In 1904 Schaudinn suggested that possibly the parasite of yellow fever would eventually prove to be a spirochete. Arguing on his premises regarding the life cycle of spirochetes, this suggestion seemed to be a valuable one, but Novy's work appears to me to have weakened it somewhat

Later Novy and Knapp⁸ state

Transmission of spirillar diseases by insects, and the congenital infection of mammals and eggs of insects are proper ties which up to the present have been regarded as characteristic of protozoa. These properties are now known for the first time to be shared by this group of bacteria. Yellow fever presents a marked analogy to the spirillar infections and it is not improbable that the cause of this disease will be found to belong to this group of organisms

Again (on pages 302-303) they say

The fact alluded to above finds a remarkable parallel in the causative agent of yellow fever, which likewise disappears from the blood in about two days. It goes to show that this unknown organism may be related to the spirochetes (namely, *Spirilla*, from their point of view), and as such, may belong not to the protozoa, as is generally accepted, but to the bacteria

Every suggestion and every analogy which can possibly be brought forward in connection with yellow fever is to be welcomed, and the suggestions just quoted are, therefore more than justified. At the same time it may be pointed out that this suggestion, which, of course,

⁸ Marchoux and Salimbeni. La spirillose des poules. Ann de l'Inst. Pasteur September 1903 vol xvii pp 503-530

⁹ Marchoux and Simond. Etudes sur la fièvre jaune. Ann de l'Inst. Pasteur January 1906 vol xx pp 16-40

may prove to be correct, is somewhat contraindicated by certain facts namely, by the long period of incubation in the mosquito.

Let us speculate on the life cycle of the parasite of yellow fever so far as reasonable biologic analogy would seem to justify us at present.

Note, first of all, that the incubation of the disease in man is very short when compared with its incubation in the mosquito, hence this fact seems to call for a parasite with very rapid reproduction. Note, further, that the non-sexual reproduction, both of bacteria and of protozoa, is potentially in geometrical progression; hence the assumption, or at least the consideration, of this non-sexual reproduction during the incubation of the disease in man seems justified. Assume, for instance, that each separate organism introduced by the mosquito gives rise to 100, to 1,000, or to 10,000 organisms within a few hours, follow this up in geometrical progression. Would not such a hypothetical case be in harmony with the short incubation in man? Note, however, the important fact that in the hypothesis, up to this point, either bacteria or protozoa could present the required conditions. The fact that the organisms in question disappear early from the blood does not seem to me to be a very strong point either for or against either the bacterial or the protozoan nature of the parasite.

Passing now to the mosquito, note, first of all, the relatively long period of incubation, of about 12 days. This must have some significance.

Let us first assume, for the sake of argument, that yellow fever is caused by a spirillum, namely, from the standpoint of Novy and Knapp, by one of the bacteria. When a mosquito bites a yellow-fever patient in the early stage of the disease she drinks in these bacteria with the blood, according to present conceptions, this blood first passes to the diverticula of the esophagus and later to the stomach. The point is clear that the diverticula have become infected with the yellow fever parasite. The probabilities that all the bacteria would leave the diverticula with the blood and pass to the stomach, leaving the diverticula yellow fever sterile, seem very, very, remote, on the contrary the probabilities seem very great that some of these bacteria would remain in the diverticula.

The most recent conception of the process of biting on the part of mosquitoes is that after piercing the skin with their mouth parts they eject the contents of the diverticula into the wound. This conception seems to be based on rather good experimental evidence interpreted by a good observer (Schaudinn). If this conception is correct, it would appear reasonable to suppose that if the mosquito bites a non-immune at any time from 2 to 11 days after she has become infected from a yellow fever patient she would vomit some of the yellow fever bacteria from her esophageal diverticula into the person bitten and that this person would contract yellow fever. This conclusion is not however, in harmony with the 12-day period of incubation in the mosquito and would appear to indicate an error in the assumption that the parasite is a bacterium.

If however, it is assumed that the parasite of yellow fever undergoes part of its life cycle in the mosquito the changes in question would naturally begin very shortly after the organisms gained access to the mosquito and under such supposition they would probably not result in yellow fever even if vomited from the esophageal diverticula into a non-immune because their life cycle in the mosquito has not been completed.

Novy and Knapp⁵ have insisted that we have as yet absolutely no evidence that *Spirillum duttoni* and *Spirillum gallinarum* do undergo any necessary cycle or even a multiplication in ticks, and at least the first part of this claim seems well founded. Have we not, on the other hand, a certain amount of indirect evidence in the 12-day incubation period that the yellow fever parasite does undergo part of its normal life cycle in the mosquito?

Since we have at present no analogy of such obligatory alternate cycles among the bacteria, and since we have good analogies for such cycles among the protozoa, does not this obligatory period of incubation seem, in our present state of knowledge, and, of course, without prejudice to any unknown cycles in bacteria to indicate that the parasite in question is of protozoal rather than of protophytic nature?

So far as our present knowledge of unicellular organisms goes I believe that to-day as in 1901, the indications are that yellow fever is caused by a protozoon, but I am in doubt as to its exact systematic position, namely, whether it is a sporozoon or a flagellate. If, however, double life cycles can be proved for any of the bacteria, then the present data regarding yellow fever will be equally applicable to the view that the disease is caused by some sort of a bacterium.

What now, is the meaning of the double life cycle, the alternation of sexual and non-sexual reproduction?

Years ago academic protozoology showed that in certain protozoa the non-sexual reproduction is limited in extent and is rapid, while the sexual reproduction may be still more limited in extent and is slower in comparison.

Just why this limitation exists, whether the non-sexual reproduction is brought to an end because of the animals' becoming exhausted, from a reproductive standpoint (perhaps an internal cause), or because of unfavorable surroundings (an external cause), or from a combination of both, can not be discussed here, fundamental as the question is. Suffice it to say that the non-sexual reproduction in many unicellular animals is limited in extent. It is fortunate for us that this is so, for were it not every untreated case of malaria would necessarily be fatal, since the organisms in man increase (potentially) in geometrical progression. Note the important point however that in malaria, caused by a parasitic protozoon this non-sexual reproduction is rapid while it lasts but that it is limited in extent by some factors not altogether clear at present.

The exact causes of this limitation of non-sexual reproduction among the protozoa calls for extensive academic study, but the results of such study will be of far-reaching practical importance.

CHRONIC GASTRITIS*

RICHARD F. CHASE, M.D.

Instructor in Clinical Medicine and Lecturer in Gastrointestinal Diseases Tufts College Medical School Physician to the Boston Dispensary
BOSTON

Probably no term employed in the nomenclature of gastric diseases has been more misused than that of chronic gastritis. The disease has been and still is considered by some physicians a very common affection yet Riegel says: "Chronic catarrh of the stomach is not a frequent disease. If we cease to force all

* Read in part at a meeting of the Massachusetts Medical Society.

disorders into a few disease categories, and rely only on positive signs of this condition, we shall soon learn that chronic gastritis is not so frequent as older physicians thought and as many modern ones still persist in believing." Stockton¹ says that "the comparative infrequency of chronic gastritis will be endorsed by experience if the cases are carefully studied." In my experience, primary chronic gastritis is encountered once in about every 300-400 adult patients in a general medical clinic, not so often as gastric cancer or gastric ulcer. Of 100 consecutive cases of gastric disorders, taken from my private records in which the stomach contents were examined, 9 presented the objective findings of chronic gastritis. This percentage (9 per cent) of gastritis cases is greater than I had expected to find, but it should be stated that more than one-half of the number from which these were taken were cases referred by physicians and represent unusually severe types of gastric affections.

With the general practitioner the percentage of such cases is probably somewhat larger than is met in a clinic, for the reason that he does not see so many patients with trivial ills. Yet, however we approach the subject, it will be found that the percentage of cases of primary chronic gastritis is comparatively small.

DEFINITION OF CHRONIC GASTRITIS

Because the above statements will seem surprising, perhaps incredible to some, let us come to an understanding of what is meant by chronic gastritis, and how the condition may be recognized. Briefly, then, chronic gastritis means a chronic inflammation of the gastric mucosa, an organic affection characterized by certain pathologic changes. This condition produces certain alterations in the gastric secretion, usually a diminution of the acidity, with more or less impairment of the ferments pepsin and rennin, and there is usually an excessive secretion of mucus. The degree of alteration of the secretion depends on the extent and severity of the inflammatory process. Now, by certain well-known tests we are enabled to detect the changes occurring in the secretions, and it is on these objective findings that we base our diagnosis. It was the custom in the past to base the diagnosis of this condition on the subjective symptoms of the patients. This older method has frequently resulted in the diagnosis of chronic gastritis in cases which have been proved to be cancer, ulcer, neuroses and other gastric conditions.

Herein lies the explanation for the prevalence of the different opinions regarding the occurrence of this disease. The original purpose of this paper was to consider the occurrence and etiology of gastritis, but since so little has been written on this subject, as compared to other features of digestive diseases, a further discussion of the disease may not be out of place, and the 9 cases referred to will help to present some points I desire to make.

DURATION

In chronic gastritis the duration of the condition is known to be considerable. The average duration in the 9 cases exceeded six years, the shortest being over one year and the longest over twenty years from the beginning of symptoms.

SEX AND AGE

The disease is more common in men than in women. These cases reported occurred in patients between the

ages of 20 and 50 years. Ewald² considers that a large number of patients who are said to die of old age, really perish from gastric atrophy, but states that this is not generally recognized, since the symptoms are as yet not well known and because the microscopic changes in the stomach are not marked. Of the few elderly patients in whom I have suspected this condition, I have usually been surprised to find no evidence of it.

ETIOLOGY

So many factors enter into the etiology of the disease that it is often difficult or impossible to attribute the condition to any single cause. The use of alcohol is considered by many as the most common cause, and it seems probable that this agent, by its direct action either on the gastric mucosa, or the liver and other organs, may cause primary, or secondary chronic gastritis. The majority of my patients with gastritis have not used alcoholic liquors to excess, and many have not used them at all.

WEIGHT

It is the popular opinion that patients with gastritis are usually emaciated or show considerable loss of weight. Strumpell³ speaks of it, and Ewald says "Emaciation soon occurs, and losses of from 30 to 60 pounds may often occur in a few weeks." On the other hand, Einhorn⁴ states that "although there are exceptions to this rule, the general appearance is good, the patient looks well nourished and usually possesses a good panniculus adiposus."

Of the 9 cases cited (with an average duration exceeding six years) three patients had lost less than 5 pounds, and but one more than 10 pounds, my general experience coincides with Einhorn's.

OTHER SYMPTOMS

Appetite—This is generally considered as diminished, although most writers mention exceptions to the rule. I find that only one patient complained of poor appetite, four considered their appetites good, and four that their appetites varied from excessive to voracious. With good appetites and fairly good vicarious digestion by the intestines there is but little reason for much loss of weight.

Pain—In only 2 of the 9 cases was pain complained of. In 1 of these cases it occurred from one to two hours after eating and was relieved by eating again. This case has been referred to in another article,⁵ and is one of several of this kind which I have observed. Boas⁶ refers to this peculiar type of pain in chronic gastritis, and remarks that "it has exactly the same character as the pain in hyperchlorhydria," with which statement I quite agree. Pain as a rule, however, is the exception.

Bowels—Constipation occurred in 4 cases, while in 5 the bowels were regular. Constipation is considered the rule. Distress or discomfort (not pain) after meals occurred in 5 cases. This I find is a fairly common symptom. Excessive flatulence occurred in 3 cases, and was usually an annoying and obstinate symptom to overcome. Eructation of gas, with or without regurgitation, also occurred in 3 cases, as did also nausea and vomiting, which was soon relieved by treatment.

Thus it is seen that no one symptom, nor any particular group of symptoms is characteristic of gastritis,

moreover, any symptom, or almost any group of symptoms, here mentioned may result from a neurosis, or an organic disease other than gastritis. It should be borne in mind that purely nervous symptoms may occur in cases of gastritis.

DIAGNOSIS

The diagnosis must be based on the objective findings obtained from examination of the gastric contents, yet it is rarely safe to make a positive diagnosis from a single examination. I shall not enter into the details of diagnosis, they may be found in any recent work on diseases of the stomach.

In these 9 cases, free HCl was absent on repeated examinations, and combined HCl was, as a rule, diminished, with a corresponding reduction in total acidity. Mucus was present in excessive amounts in 7 of the 9 cases. Except in 3 cases of slight stasis, the amount of contents one hour after an Ewald test breakfast was always diminished, and in the majority of patients no contents could be obtained at the expiration of this period. "Acid gastritis" and secondary gastritis are not considered here.

Differential Diagnosis—Nervous achlorhydria, some cases of cancer of the stomach and achylia gastrica are the conditions with which gastritis is most often confused when considering the gastric contents. Cases of transient achlorhydria are easily distinguished by observation, as the secretion soon returns in full strength, whereas the return of the secretion in chronic gastritis is always gradual and rarely or never appears in normal amount. Cancer is soon distinguished after observation by the continued loss of weight and the certain downward progress of the patient. The chemical findings of achylia gastrica can not be distinguished from those of atrophic gastritis, from which condition the achylia may and usually does result, although we occasionally see a case, one of which I have briefly reported,⁷ in which it is difficult to conceive of a pre-existing gastritis, since there are no symptoms.

COMPLICATIONS

A slight degree of stasis or motor insufficiency was observed in 3 of these 9 cases, it was soon overcome by treatment. I believe that marked degrees of stasis or atony rarely occur in uncomplicated cases of gastritis.

Hypermotility or pyloric insufficiency occurred in six of the patients, as indicated by the absence of gastric contents one hour after an Ewald test breakfast. In so far as I know, it has never been positively determined whether this premature expulsion of contents results from hypermotility, or from an insufficient pylorus. A factor to be considered in this condition is the fact that the diminished secretion naturally causes a diminution in the amount of contents. Whatever the condition may result from I have found it a difficult or impossible one to overcome, although in some cases in which the secretion has been restored, more gastric contents have been obtainable at later periods after the test meal than at the beginning of treatment. Some observers look on this condition merely as a compensatory one whereby the chyme is hurried into the intestines where the greater part of digestion occurs. If viewed in this light it is not a condition to be overcome.

PROGNOSIS

Riegel says "Mild degrees of gastritis may be cured and frequently are cured. If severe degrees of atony

have developed the prognosis is less favorable." According to Ewald, "the prognosis of this disease should not be considered too slightly, especially as in prolonged cases of atrophy, an incurable and fatal lesion may be developed. Even in apparently cured cases the organ is left in such a sensitive condition that the slightest irritation or deviation from a specified diet may cause a fresh attack."

I believe that practically all patients with gastritis may be relieved of their subjective symptoms. Even in cases of achylia with gastric atrophy such results are often obtained, and these patients are seen to follow their occupations, to eat almost any kind of food with little or no discomfort, and to maintain their standard weight. In a large percentage of the simple and mucous forms of gastritis, the subjective symptoms are not only overcome, but the free HCl (which may have been absent for months or years judging from the duration of the symptoms) may be restored, at least in part. Such results may certainly be considered as cures.

It would seem that relapses are liable to occur in this disease, yet I have encountered only an occasional case, and in each, gross indiscretion in diet or the excessive use of liquor seemed the probable cause. During treatment most patients learn a valuable lesson in dietetics and profit thereby. For this reason I feel that they may be less liable to a recurrence than many individuals, who daily abuse their stomachs, are to the disease. The nine patients cited were treated from one month to several months. In every case the subjective symptoms were relieved or entirely overcome within a few weeks.

In 6 of the 9 cases free HCl was restored in amounts from 2-5 of one part per 1,000 or 0.2-0.5 of 1 per cent. The return of the HCl was always a gradual process at first merely a trace appeared and later amounts sufficient to titrate. The earliest return of HCl in any case was after eleven days' treatment, while the longest time required for its appearance was seven months of irregular treatment. The average time of total treatment was about three months.

The results of treatment in those cases in which HCl was not restored seemed quite as satisfactory as in those in which it returned, in so far as relief from symptoms was concerned. At the time of discharge all these patients were partaking of a plain, wholesome diet. During the period of from twelve to nineteen months since their discharge, six of these patients have reported no recurrence of symptoms and in 5 of the cases in which the HCl was restored it is still present. Three cases have not been followed.

It may be argued that these cases were unusually mild ones (the average duration was six years), yet I consider them fairly representative of the class of gastritis cases usually encountered. The question may arise, how long after the disappearance of subjective symptoms is one justified in treating a case in an attempt to restore the secretion? It may be said generally that the stronger or the richer the secretion the greater the possibility of restoring it to normal.

The strength of a secretion is best ascertained by the result of the quantitative test of its rennin or rennin-zymogen. Boas⁸ and Bourver⁹ have determined that normally rennin-zymogen after the addition of calcium chloride will coagulate milk with a dilution of 1 part secretion to from 150 to 160 parts water. Hence the

⁷ Philadelphia Med Jour., June 14 1902.

⁸ Deutsch. Med. Woch. chr.,
⁹ Gaz. Méd. de Paris No. 22

greater the dilution of a secretion, and a positive result from this test, the stronger it is. The above-mentioned writers have further decided that "a secretion which will not coagulate milk, after a 1-25 dilution, indicates a condition of advanced atrophy, in which there is but little probability that the gastric secretion can be restored." Usually the free HCl returns, if at all, within a few weeks.

One of the objects of treatment is to restore the secretion as nearly as possible to its normal strength, consequently so long as examinations from time to time show an increase in the amount of HCl, treatment should be continued. I have found, however, that after the free HCl has reached the strength of about 0.5 of 1 part per 1,000, or 0.5 of 1 per cent, continued treatment fails to effect a further increase. I have never seen or heard this point discussed, therefore I do not know if mine has been a common experience with others.

TREATMENT

The object of treatment is to overcome the inflammation and if possible to restore the secretion and the impaired motor power of the stomach. Since any single cause of the inflammation is rarely discoverable, we must remove all conditions which may be considered as contributing factors. Hence, good hygiene is advised, which means regular habits as to eating, exercise and action of the bowels, repair of carious teeth, etc.

Diet—In this condition starches are better digested in the stomach than under normal conditions, while proteids are but poorly cared for here, being digested almost entirely in the intestines. Bearing this point in mind and remembering that all mechanical, chemical and thermal irritants are to be avoided, we have the key to dietetics in this disease.

The articles of food to be allowed I check from a printed diet list, usually advising three meals a day, with one or two lunches if desired. Of the more restricted diet in the beginning of treatment, patients will rarely eat too much, while if the scales show a maintenance or increase of weight I feel that they are eating enough, regardless of the number of calories which the food represents. Cooked fats I have found are not usually well borne. No alcoholic liquors are allowed, my reasons for prohibiting them are given elsewhere.¹⁰

Mechanical Means—To free the stomach of mucus and to stimulate secretion and peristalsis, douching of the stomach internally with a warm alkaline and saline solution, is, I believe, the most valuable means we possess. For this purpose I employ my stomach apparatus,¹¹ using the Rosenheim tube. The solution is injected with the amount of force desired, but it is always greater than that obtained by ordinary lavage. By the douche I believe that adherent mucus is more thoroughly removed than by simple lavage, while the stimulating action of the small forceful streams must be far greater than that produced by pouring water into a tube which has but one or two large eyes. In fact, I feel that douching of the stomach in gastritis and other conditions will become a more popular means of treatment when its technic and results are better known.

Riegel agrees that "the internal douche may frequently be employed with profit in chronic gastritis. It may be useful under certain conditions to force the fluid into the stomach under pressure." Douching or lavage should

be done at least twice a week and always with the fasting stomach. The agents which I usually employ are sodium chlorid and sodium bicarbonate 30 grains of each to a pint of water at 100° F. "Washing out" the stomach with copious draughts of medicated water seems but a poor substitute for douching.

Drugs—For the purpose of dissolving mucus and in creasing the secretion I use from 10 to 15 grains each of sodium chlorid and sodium bicarbonate in a glass of warm water, to be taken about fifteen minutes before meals. Some of the saline mineral waters may serve the same purpose in a measure, so also may some of the more elegant preparations containing the various salts. The phosphate or sulphate of sodium may be used, especially if there is constipation, *nux vomica*, *condurango* and other bitter tonics may be of service, but of late I have rarely used them.

I have elsewhere expressed my views regarding the use of hydrochloric acid¹² and pepsin.¹³ I believe that the large doses of from 15 to 20 minims of HCl fail to accomplish the desired object, moreover, I feel that they may do harm. Small doses of from 5 to 10 minims may in some ways prove beneficial, but I consider that there is no evidence to show that they stimulate the secretion of HCl.

Vacations and out-of-door exercise or occupation are important and at times seemingly necessary factors in the cure of gastritis.

A GRAPHIC METHOD IN PRACTICAL DIETETICS

IRVING FISHER, PH.D.

Professor of Political Economy Yale University and Secretary of the New Haven County Anti-Tuberculosis Association
NEW HAVEN, CONN.

Professor Mendel, in an address on dietetics before an audience of Boston physicians, asked the very pertinent question "Why do physicians take so much care in measuring their dosages of drugs, which are administered only occasionally, and so little care in measuring their food prescriptions, which are to be followed daily?" In prescribing drugs, a physician would be regarded as criminally negligent if he simply told his patients to take "a little" strychnia, but to be sure "not to take too much," or to take a "big dose" of calomel. Yet in prescribing diet, physicians often give just such advice.

Doubtless in the scheme of Nature man was not expected to measure his food. He was provided with healthy, normal instincts instead. But, as often happens in diseased conditions, the food instinct has sometimes become perverted and can not be trusted. The consumptive requires, or at any rate is believed by most physicians to require, more food than his appetite calls for, and the victim of kidney diseases less. To re-establish the instinctive guides to food selection should doubtless be the ultimate aim of the physician, but, to that end, a quantitative determination of the food actually used, and a quantitative regulation thereof, may be advantageously employed. As yet, however, neither the quantity of food nor the proportions of its constituents have been often prescribed with precision.

¹⁰ Philadelphia Med. Jour. June 6 1903.

¹¹ An Improved Stomach Tube. THE JOUR. A. M. A., July 28 1906.

What Dr. Burton-Tanning says of pre-cisibing food for the consumptive applies to food pre-scriptions in general, that the whole art of such pre-scriptions is summed up in the word accuracy.¹ Until recently accuracy was impossible. But to-day by the aid of elaborate tables of food values constructed by Atwater and Bryant in America and of mineral salts by Koenig in Germany and if great accuracy is required of coefficients of digestibility it has become possible to make a true measurement of diet prescriptions.

As to mineral salts we know at least in which foods they are severally to be found. For instance if a patient needs iron he may instead of taking the preparations of the druggist have added to his list of foods one or more of the following lentils asparagus, lettuce peas figs strawberries, spinach, beans, potatoes prunes or apples, the order of which is that of the amount of iron contained in proportion to total food value.

Again, if calcium is needed instead of limewater there may be administered milk figs cabbage or lentils. If sulphur is needed, the patient may be given potatoes peas, beans asparagus or cabbage, if phosphorus beans, peas, rice, milk, if silicon, lettuce cabbage strawberries rice potatoes barley or cucumbers if magnesium peas beans coconuts, barley and rice, if chlorine, coconuts milk lentils, asparagus cabbage, if sodium lentils figs asparagus if potassium beans, lentils peas, coconuts, potatoes. Or if simply mineral salts in general are required, they are found in large quantities in proportion to food value among lentils peas beans coconuts potatoes, milk rice figs, apples, barley cabbage and chestnuts.

There are data also which describe the amount and kinds of acids in foods their peptogenic qualities, their effects on peristalsis, etc.

THE BASIS OF COMPUTATION

But the ordinary problems of dietetics are concerned not so much with these minor constituents and properties of foods as with the amount and proportions of proteids fats and carbohydrates.

Two methods have hitherto been used for computing proportions of proteids, fats and carbohydrates. One consists in using the tables of percentages by weight of proteids, fats and carbohydrates, the other, Dr. J. H. Kellogg's, in using a table which gives the number of calories in the form of proteids, fats and carbohydrates per ounce of each kind of food. These may be described respectively, as the method of weight per cent, and the method of calories per ounce. The method here suggested is different from either, and may be called the method of calories per cent. It takes as its starting point not a unit of weight but a unit of food value called a "standard portion" of each kind of food. A "standard portion" is defined as that amount of food which contains 100 calories. A table is constructed which gives the weight in a "standard portion" of each particular kind of food, and out of the 100 calories contained therein the number of calories in the form of proteids, fats and carbohydrates. The three methods were discussed and the last named explained in detail in another paper.² We shall, therefore, pass over this part of

our subject very briefly in the present paper and devote our main attention to the practical application.

In order to carry out this method foods should be served at the table in "standard portions" or simple multiples thereof. The amount of milk served instead of being a whole number of ounces should be (for average milk) 4.9 ounces—the amount that contains 100 calories. This "standard portion" constitutes about two-thirds of an ordinary glass of milk. Of the 100 calories which it contains 19 will be in the form of proteid 52 in fat and 29 in carbohydrates. In other words of the food value of milk 19 per cent is proteid 52 per cent fat and 29 per cent carbohydrates.

One advantage of this method is apparent at once. It enables us to make a true comparison between different foods as to the relative amounts of proteid fat and carbohydrate. The other methods are misleading in this regard. For instance though it is well recognized that milk is a higher proteid food than pecan nuts, yet if we compare milk and pecans on the basis of the method of "weight per cent" we shall find that the pecans appear three times as rich in proteid milk containing 33 per cent and pecans 11 per cent. But if we compare them on the basis of "calories per cent" we find that while milk contains 19 calories of proteid out of each 100 of total calories pecans contain only 6 milk showing three times as much proteid as pecans. The paradox that pecans are higher in proteid per ounce but lower in proteid per 100 calories is due to the fact that pecans are a much more concentrated food than milk whereas 100 calories of milk weigh 4.9 ounces 100 calories of pecans weigh only half an ounce. The weight of a "standard portion" of any food is a measure of the degree of concentration. The most concentrated of all foods is probably olive oil which contains 100 calories in a little over one-third of an ounce (38.07). Watermelon represents a food at the opposite extreme of which over 11½ pounds are required to yield the 100 calories. In order that the "calories per cent" method may be easily put in practice it is necessary to have a table giving the weight constituting a "standard portion" (i.e. the amount yielding 100 calories) and the calories of proteid fat and carbohydrate in this portion. At the close of the present article such a table is given, computed chiefly from the tables of Atwater and Bryant and for made dishes from those of Dr. Kellogg. The chief advantage of this method of expressing food values is that it lends itself readily to graphic representation. The difficulty in the practical use of the values is that they can not be visualized.

THE GRAPHIC METHOD

Different foods contain the three food triads fats and carbohydrates, in different proportions. The tripartite constitution of any particular food is represented in the present method by the point in the triangle CPF (Fig. 1). The method of plotting the point on the triangle is analogous to that of plotting a point on a map by latitude and longitude, the percentage of proteid in the food is represented like latitude the height of the point above the base line CF (the height CP, being taken as 100 per cent). The percentage of fat is represented, like longitude, by the distance

¹ For convenience the triangle is drawn with one angle a right angle and the two sides about it equal.

² I am of the opinion that although the table of the present paper is not perfect (i.e., 2% error in the value for proteid).

1 For a statement of the great divergences of opinion from this ideal see "Statistics of Diet in Consumptive Cases," Fisher Trans. Second Annual Meeting Nat. Assoc. for Study and Prevention of Tuberculosis, New York, 1907 also in Am. Jour. of the Med. Sci., October 1906.

2 Fisher "A New Method for Indicating Food Values," Am. Jour. of Physiol., April 1 1909.

greater the dilution of a secretion, and a positive result from this test, the stronger it is. The above-mentioned writers have further decided that "a secretion which will not coagulate milk, after a 1-25 dilution, indicates a condition of advanced atrophy, in which there is but little probability that the gastric secretion can be restored." Usually the free HCl returns, if at all, within a few weeks.

One of the objects of treatment is to restore the secretion as nearly as possible to its normal strength, consequently so long as examinations from time to time show an increase in the amount of HCl, treatment should be continued. I have found, however, that after the free HCl has reached the strength of about 0.5 of 1 part per 1,000, or .05 of 1 per cent, continued treatment fails to effect a further increase. I have never seen or heard this point discussed, therefore I do not know if mine has been a common experience with others.

TREATMENT

The object of treatment is to overcome the inflammation and if possible to restore the secretion and the impaired motor power of the stomach. Since any single cause of the inflammation is rarely discoverable, we must remove all conditions which may be considered as contributing factors. Hence, good hygiene is advised, which means regular habits as to eating, exercise and action of the bowels, repair of carious teeth, etc.

Diet—In this condition starches are better digested in the stomach than under normal conditions, while proteids are but poorly cared for here, being digested almost entirely in the intestines. Bearing this point in mind and remembering that all mechanical, chemical and thermal irritants are to be avoided, we have the key to dietetics in this disease.

The articles of food to be allowed I check from a printed diet list, usually advising three meals a day, with one or two lunches if desired. Of the more restricted diet in the beginning of treatment, patients will rarely eat too much, while if the scales show a maintenance or increase of weight I feel that they are eating enough, regardless of the number of calories which the food represents. Cooked fats I have found are not usually well borne. No alcoholic liquors are allowed, my reasons for prohibiting them are given elsewhere.¹⁰

Mechanical Means—To free the stomach of mucus and to stimulate secretion and peristalsis, douching of the stomach internally with a warm alkaline and saline solution, is, I believe, the most valuable means we possess. For this purpose I employ my stomach apparatus,¹¹ using the Rosenheim tube. The solution is injected with the amount of force desired, but it is always greater than that obtained by ordinary lavage. By the douche I believe that adherent mucus is more thoroughly removed than by simple lavage, while the stimulating action of the small forceful streams must be far greater than that produced by pouring water into a tube which has but one or two large eyes. In fact, I feel that douching of the stomach in gastritis and other conditions will become a more popular means of treatment when its technique and results are better known.

Riegel agrees that "the internal douche may frequently be employed with profit in chronic gastritis. It may be useful under certain conditions to force the fluid into the stomach under pressure." Douching or lavage should

be done at least twice a week and always with the fasting stomach. The agents which I usually employ are sodium chlorid and sodium bicarbonate 30 grains of each to a pint of water at 100 F. "Washing out" the stomach with copious draughts of medicated water seems but a poor substitute for douching.

Drugs—For the purpose of dissolving mucus and increasing the secretion I use from 10 to 15 grains each of sodium chlorid and sodium bicarbonate in a glass of warm water, to be taken about fifteen minutes before meals. Some of the saline mineral waters may serve the same purpose in a measure, so also may some of the more elegant preparations containing the various salts. The phosphate or sulphate of sodium may be used, especially if there is constipation, *nux vomica*, *condurango* and other bitter tonics may be of service, but of late I have rarely used them.

I have elsewhere expressed my views regarding the use of hydrochloric acid¹² and pepsin.¹³ I believe that the large doses of from 15 to 20 minims of HCl fail to accomplish the desired object, moreover, I feel that they may do harm. Small doses of from 5 to 10 minims may in some ways prove beneficial, but I consider that there is no evidence to show that they stimulate the secretion of HCl.

Vacations and out-of-door exercise or occupation are important and at times seemingly necessary factors in the cure of gastritis.

What Dr. Burton-Fanning says of prescribing food for the consumptive applies to food prescriptions in general, that the whole art of such prescriptions is summed up in the word accuracy.¹ Until recently accuracy was impossible. But to-day, by the aid of elaborate tables of food values constructed by Atwater and Bryant in America, and of mineral salts by Koenig in Germany, and if great accuracy is required, of coefficients of digestibility, it has become possible to make a true measurement of diet prescriptions.

As to mineral salts we know at least in which foods they are severally to be found. For instance, if a patient needs iron, he may, instead of taking the preparations of the druggist, have added to his list of foods one or more of the following: lentils, asparagus, lettuce, peas, figs, strawberries, spinach, beans, potatoes, prunes or apples, the order of which is that of the amount of iron contained in proportion to total food value.

Again, if calcium is needed, instead of limewater there may be administered milk, figs, cabbage or lentils. If sulphur is needed, the patient may be given potatoes, peas, beans, asparagus or cabbage, if phosphorus, beans, peas, rice, milk, if silicon, lettuce, cabbage, strawberries, rice, potatoes, barley or cucumbers; if magnesium, peas, beans, cocoanuts, barley and rice, if chlorine, cocoanuts, milk, lentils, asparagus, cabbage, if sodium, lentils, figs, asparagus, if potassium, beans, lentils, peas, cocoanuts, potatoes. Or if simply mineral salts in general are required, they are found in large quantities in proportion to food value, among lentils, peas, beans, cocoanuts, potatoes, milk, rice, figs, apples, barley, cabbage and chestnuts.

There are data also which describe the amount and kinds of acids in foods, their peptogenic qualities, their effects on peristalsis, etc.

THE BASIS OF COMPUTATION

But the ordinary problems of dietetics are concerned not so much with these minor constituents and properties of foods as with the amount and proportions of proteids, fats and carbohydrates.

Two methods have hitherto been used for computing proportions of proteids, fats and carbohydrates. One consists in using the tables of percentages by weight of proteids, fats and carbohydrates, the other, Dr. J. H. Kellogg's, in using a table which gives the number of calories in the form of proteids, fats and carbohydrates per ounce of each kind of food. These may be described respectively, as the method of weight per cent and the method of calories per ounce. The method here suggested is different from either, and may be called the method of calories per cent. It takes as its starting point not a unit of weight but a unit of food value called a "standard portion" of each kind of food. A "standard portion" is defined as that amount of food which contains 100 calories. A table is constructed which gives the weight in a "standard portion" of each particular kind of food, and out of the 100 calories contained therein the number of calories in the form of proteids, fats and carbohydrates. The three methods were discussed and the last named explained in detail in another paper.² We shall, therefore, pass over this part of

our subject very briefly in the present paper and devote our main attention to the practical application.

In order to carry out this method foods should be served at the table in "standard portions" or simple multiples thereof. The amount of milk served instead of being a whole number of ounces, should be (for average milk) 4.9 ounces—the amount that contains 100 calories. This "standard portion" constitutes about two-thirds of an ordinary glass of milk. Of the 100 calories which it contains, 19 will be in the form of proteid, 52 in fat, and 29 in carbohydrates. In other words of the food value of milk 19 per cent is proteid, 52 per cent fat, and 29 per cent carbohydrates.

One advantage of this method is apparent at once. It enables us to make a true comparison between different foods as to the relative amounts of proteid, fat and carbohydrate. The other methods are misleading in this regard. For instance, though it is well recognized that milk is a higher proteid food than pecan nuts, yet if we compare milk and pecans on the basis of the method of "weight per cent" we shall find that the pecans appear three times as rich in proteid, milk containing 3.3 per cent and pecans 11 per cent. But if we compare them on the basis of "calories per cent," we find that while milk contains 19 calories of proteid out of each 100 of total calories, pecans contain only 6, milk showing three times as much proteid as pecans. The paradox that pecans are higher in proteid per ounce but lower in proteid per 100 calories is due to the fact that pecans are a much more concentrated food than milk, whereas 100 calories of milk weigh 4.9 ounces, 100 calories of pecans weigh only half an ounce. The weight of a "standard portion" of any food is a measure of the degree of concentration. The most concentrated of all foods is probably olive oil, which contains 100 calories in a little over one-third of an ounce (.38 oz.). Watermelon represents a food at the opposite extreme of which over 1 1/2 pounds are required to yield the 100 calories. In order that the "calories per cent" method may be easily put in practice it is necessary to have a table giving the weight constituting a "standard portion" (i.e., the amount yielding 100 calories) and the calories of proteid, fat and carbohydrate in this portion. At the close of the present article such a table is given, computed chiefly from the tables of Atwater and Bryant and for made dishes from those of Dr. Kellogg. The chief advantage of this method of expressing food values is that it lends itself readily to graphic representation. The difficulty in the practical use of most tables of food values is that they can not be visualized.

THE GRAPHIC METHOD

Different foods contain the three food elements, proteids, fats and carbohydrates, in different proportions. The tripartite constitution of any particular food is represented in the present method by the position of a point in the triangle CPT (Fig. 1). The method of locating the point on the triangle is analogous to that of locating a city on a map by latitude and longitude: the per cent of proteid³ in the food is represented like latitude by the height of the point above the base line CT (the total height CP being taken as 100 per cent). The percentage of fat is represented, like longitude, by the distance

1. For a statement of the great divergences of sanatoria from this ideal see *Statistics of Diet in Consumptive Sanatoria*, Fisher Trans. Second Annual Meeting Nat. Assoc. for Study and Prevention of Tuberculosis, New York, 1907, also in *Am. Jour. of the Med. Sci.*, October, 1906.

2. Fisher, "A New Method for Indicating Food Values," *Amer. Jour. of Physiol.*, April 1, 1906.

3. For convenience the triangle is drawn with one angle a right angle and the two sides about it equal.

4. I employ the term proteid although in the table the figures represent protein (i.e., 61.4 times nitrogen) the usual nomenclature for proteid.

of the point horizontally from the vertical line CP (the total horizontal breadth, CF, being taken as 100 per cent). Thus, the point O, representing milk, is located at a height above CF ("latitude") 19 per cent of the total height of the triangle, which signifies that 19 per cent of the food value of milk is proteid, and at a distance to the right of CP ("longitude") 52 per cent of the total breadth of the triangle, which signifies that 52 per cent of the food value of milk is fat. Foods high in proteid will be represented by points high up in the triangle. White of egg, of which the food value is all proteid, will be represented at the point P, representing 100 per cent. P is, therefore, called the "proteid corner" of the triangle. Foods rich in fats, as nuts, cream, butter are represented by points far to the right. Pure fats like olive oil are located at F at the extreme right, representing 100 per cent of fat. F is, therefore, called the "fat corner."

The point representing a food is completely located by means of the percentage of proteid and fat, no attention need be paid to the carbohydrate. If, however, it is desired to find the carbohydrate, its percentage is readily determined being what is left of 100 calories not already accounted for by proteid and fat. Thus a "standard portion" of cottage cheese, being 76 per cent proteid and 8 per cent fat, will have left 16 per cent of carbohydrate. If one desires a graphic representation,

Figure 1

it is found in the distance of the point O from the third side of the triangle, FP (the total distance of this side from the opposite corner being taken as 100 per cent). Foods like bread, cereals and fruits, which are mostly carbohydrate, will thus be represented by points far away from the side FP. Foods such as sugar, of which the food value is wholly carbohydrate, will be represented at the remotest point C, representing 100 per cent carbohydrate, which is, therefore, called the "carbohydrate corner."

Any food is thus represented on the "food map" by a point the relative distances of which from the three sides of the triangle represent the proteid, fat and carbohydrate.⁵ On this food map, fatty foods are repre-

⁵ It has been shown elsewhere (Amer Jour of Physiol April 1906 pp 422-4) that this method of visualizing the composition of any food carries another method with it. If from the point O (Fig 1) the position of which in the triangle indicates the food composition (of milk for instance) we draw straight lines to the three corners of the triangle thus resolving the triangle into three constituent triangles. It may be shown that if we call the total area of the triangle 100 to represent a standard portion (100 calories) of the food then the three partial triangles will exactly represent the constituents for proteid, fat and carbohydrate. The triangle representing proteid is COF i.e. the triangle whose altitude to O represents proteid in the first method. Similarly COP represents fat and POF carbohydrate. For the graphic representation of particular foods by this method of triangles see the article already cited. In the present article only the method of lines or as we may call it, the "latitude and longitude" method will be employed.

sented by points near the fat corner, F, starchy and saccharine foods by points near the carbohydrate corner, C and proteid foods by points near the proteid corner, P. A food devoid of proteid is evidently located on the base line C, a food devoid of fat, on the side CP, and a food devoid of carbohydrate on FP. The chief classes are represented in the accompanying diagrams, flesh foods and cereals being shown in Figure 2, nuts and fruits in Figure 3, vegetables in Figure 4, puddings, pies, pastries and sweets in Figure 5, dairy products, eggs and meat substitutes in Figure 6, and soups, salads and relishes in Figure 7. In each case, the position of the point relatively to the sides of the triangle represents the proportions of the proteids, fats and carbohydrates, and the number opposite each name represents the weight (in ounces) of a "standard portion."

This method of representing food values reveals some striking facts—for instance, the great variations in the proportion of proteid in different vegetables. Vegetables

Figure 2.

are commonly supposed to be low in proteid. This is true of some vegetables, such as beets, artichokes and sweet potatoes, but others are high in proteid, such as asparagus, cabbage, cauliflower, celery, cucumbers, eggplant, radishes, spinach, squash, and tomatoes.⁶ Among fruits also we find some instances of moderately high proteid, such as strawberries and blackberries, oranges and watermelon. These foods are as high in proteid, in proportion to total food value, as most nuts and cereals. On the other hand, dried fruits, which are sometimes mentioned as containing a higher percentage of proteid than other fruits, are as a matter of fact often much lower. Thus, dates contain but 2 per cent, prunes and raisins 3 per cent, figs 5 per cent.

It is evident that in most cases foods of the same class show a family resemblance. Meats and other flesh foods, with the exception of shellfish, are represented by points on FP, being devoid of carbohydrates. Cereals are represented by points near the carbohydrate corner,

⁶ It should be stated however that all estimates of proteid are strictly speaking protein. I.e. 0.8 times the contained nitrogen. In some cases proteid and protein are not identical but the former is less than the latter owing to the fact that some of the nitrogen is not in proteid but in a waste or useless form. This is true of almost all the proteid of meat soups which have therefore practically no food value except a peptogenic one. As to vegetables, in default of exact data, no correction from protein to proteid is here attempted.

C, nuts, with the exception of chestnuts, are located near the fat corner, F, fruits, with the exception of olives, near the carbohydrate corner, C, vegetables show a large range within the triangle. In Figure 8 the range of each of these classes is approximately shown

The foods eaten at a meal may thus be indicated by points on the "food map." Opposite each point should be written the amount eaten, measured in "standard portions." This array of points presents a picture of what foods and how much of each have been eaten, and shows at a glance their characteristics. But to use this properly we need to combine these points into one point,

If the calories of the two foods are unequal, the point representing the combination will be proportionately nearer the point with the larger number. Thus if one portion of bread is combined with one-half portion of butter, the bread-and-butter point will not be midway between the points for bread and for butter, but will lie twice as near the bread point as the butter point. Its approximate position may be found with great rapidity by the eye without making exact measurements.

When three foods are combined, the point representing the combination is, in like manner, the "center of gravity" of the three, and may be found by first obtain-

Figure 3.

Figure 5

Figure 4

Figure 6

their center of gravity which represents the entire meal. This may be done in various ways.

DEMONSTRATING COMBINATIONS

The combination of two foods equal in calories is represented by a point midway between them. Thus to combine one "portion" of bread and one "portion" of butter (Fig. 9) draw a straight line between their points and at the middle of it mark a cross and label it "2." This point will represent two "portions" of bread and butter

ing the center of gravity of two and then obtaining the center of gravity of the point thus obtained, and the third. Thus if as in Figure 10 we have three points representing respectively 3, 1 and 5 calories of three separate foods shown by the attached number 3, 1 and 5, the point representing the combination may be found by joining the points labelled 3 and 5, then their center of gravity 7, situated 2/3 of the way from point 3 and dividing the line from 7 to point 1 in the ratio of 3 to 4. The first two points

* Chemical Composition of American Food Materials, Atwater and Bryant, U. S. Department of Agriculture Bull. No. 28

which is drawn the right-angled triangle with which we have already become familiar. Points on this card may be located to represent the various foods employed. These points may be easily found from tables given at the end of this article. Points representing the most common foods may be already printed on it. At points representing foods eaten, pins with heavy heads are thrust through the cardboard (Fig 12), the weight of each representing one "standard portion." Similar pins, but one-half and one-quarter as heavy, are also provided to

almost instantaneously, the center of gravity is found. The total time consumed in placing the pins, adjusting the card and basket, and finding the center of gravity, is found to be, for accurate work, about five minutes.⁸

The mechanism in which the cardboard triangle is held is so arranged that when the cardboard is horizontal the center of gravity falls at a point indicating normal food proportions. If the center of gravity is at some other point, the cardboard will tip, showing that the ration is not "balanced." If the proteid vertex tips

Figure 12

Figure 14

Figure 15

represent half and quarter "portions." When these pins are placed, the total ration which has been consumed is easily found, simply by counting the "portions" thus represented. For instance, if there are 15 pins representing "standard portions" and 10 pins representing half "portions" (and therefore five full "portions"), the total ration is 20 "portions" or 2,000 calories. In order to find the percentages of proteid, fat and carbohydrate

down, it indicates an excess of proteid, if the fat vertex, excess of fat, if the carbohydrate vertex, excess of carbohydrate.

It is now evident that, by means of the mechanism and the rectangles marked on the card, it is a simple matter to discover whether a particular diet conforms to any given standard. It is equally simple to correct discrepancies thus found, and, if need be, the corrections may be made in advance and the balanced ration prescribed. A trial ration may be put on the card, and if it fails to balance, the pins may be rearranged and balanced with far greater rapidity than the corresponding operations could be carried out by arithmetical computations.

One advantage, however, of the foregoing method is that, whether the object is merely to record what is consumed or actually to prescribe, the patient need not be annoyed by having scales at table. All weighing may be done in the kitchen and the food served in "standard portions" or in known multiples or fractions of such portions. It is only necessary that the patient, or some one else, shall report exactly what part of the various portions served has been consumed. The patient need not even know the food values of the portions served to him and thus the introspection and trepidation, which often defeat the very aim of diet prescription for

Figure 13

in this ration, it is only necessary to obtain the center of gravity of all the pins. For this purpose the card is placed in a basket (Fig 13) and suspended on a standard (Fig 14) so that the center of gravity of the pins may assume a position vertically under the point of support. The position of this center of gravity is easily indicated on the card by means of a vertical prickler (Fig 15), which may be pressed on the card. Thus,

⁸ The weight of the cardboard and the basket containing it is eliminated by the construction of the basket. Its center of gravity (when containing the cardboard without pins) exactly coincides with the point of support. Hence when the basket with the card (but without pins) is placed on the point of support it is neither too heavy (which would imply static equilibrium) nor too light (which would imply static equilibrium) but is in neutral equilibrium and will remain at rest in any position in which it is placed.

the sick, may be avoided. For well persons who desire to keep a record of their dietary the method here given has the advantage that when it is once made familiar it can be employed without any apparatus. One soon becomes able to recognize the quantities of the ordinary foods which contain 100 calories, and to hold in memory the position on the triangle where these foods are indicated. A little reflection will then enable him to judge how many "standard portions" he has consumed at a meal, and also whether their center of gravity falls within the normal rectangle. If he has a good locative imagination, he can rely entirely on his mental image of the triangle. Any one who has once pictured the foods on the "food map" is not likely to forget their several locations. He will know that a meal in which soup, fish, meat, certain high-proteid vegetables, eggs, cheese, milk and ice cream predominate, must be too high in proteid, for all these foods are located above the "normal rectangle." Moreover, he will be able, after a little practice, to estimate roughly the calorific value of his food. A "portion" of 100 calories may be ascribed to each lamb chop, or its equivalent in other meat, each (large) egg, each two-thirds of a glass of milk, each ordinary potato, large slice of bread, large banana, ordinary pat or square of butter, shredded wheat biscuit or its equivalent in other cereal, eight almonds, half dozen English walnuts, one and one-half lumps of sugar, etc.

To illustrate the method by practical examples, let us suppose that for a particular patient the prescription is for 2,000 calories a day, of foods so combined that the food proportions will be represented by a point within the right half of the rectangle. To carry out this prescription the patient looks at the "food map" and finds no foods on it which themselves fall within the prescribed area. He observes, however, that bread and butter are located on opposite sides of this area, and his eye shows him that a combination of the two in equal parts (by calories, not by weight) will very nearly fall within it, though slightly too low. Corn flakes and cream combine within the set limits, milk and dates (a favorite oriental combination) fall near the mark, poached eggs on toast (with the whites left out) will also come near the proper spot, though slightly too high, any cereal foods or fruits (which lie at the left), combined with foods which lie at the right, as egg yolk, nuts or cream, butter, olives or olive oil will combine nearly right, provided the right-hand foods predominate. Choosing such of these combinations as are most relished, the patient eats his meal. Afterward he, his physician or nurse indicates on the triangle by pencil marks each food which has been eaten, or, if he has a mechanical diet indicator, by the weighted pins. The center of gravity will then show exactly where his meal is located on the "food map," and the total number of "portions" will show how much he has eaten. The cause of any deviation from the prescription will be very apparent. It may be that the point is too high, indicating excessive proteid, and this may be due to too much milk, eggs or meat, or too much cereal food may have displaced the point to the left. These errors may be rectified at the next meal. At the end of the day from the cards used in the three meals, he selects the three centers of gravity and transfers them to a fourth card from which in the same way, the total calories and center of gravity for the three are found, this represents the total day's ration.

Or, again a patient may at first be given *carte blanche* in his food, merely reporting the "portions" eaten. Each dish being served in "portions," this will require little

trouble. In fact, a nurse may do it all by noting what is put on a tray and what is left after the meal. On the basis of the returns, the physician or nurse can tell exactly how much and what proportions the patient is eating, and his besetting dietetic sins will be evident. The physician will be enabled thereby to guide him intelligently, suggesting, for instance, that he reduce his ration to two-thirds of what he has been accustomed to, or reduce meat, eggs, etc., or take more cream and butter, etc. It goes without saying that any change in diet, unless it be a change in amount only, should be gradual.⁹ Thus, if a person has been accustomed to excessive proteid, his stomach has probably become adjusted to this condition and secretes a large amount of gastric juice. When the reduction of proteid is sudden, the gastric juice will not at first decrease in proportion, and a large part of this secretion will therefore remain unused. This uncombined acid interferes with the digestion of starch and the person feels a "sour stomach." A gradual reduction of proteid, on the other hand, will avoid this difficulty. The reduction may be more rapid (for the hyperacid) if the proportion of fat is increased, as fat tends to restrain the gastric secretion.

In the winter of 1906 the mechanical diet indicator was employed for five months in an experiment with nine Yale students. No diet was prescribed, and the indicator was used only to record the diet which the men themselves chose. It was found that by following Mr. Fletcher's rules of thorough mastication and obedience to appetite, the men gradually and naturally reduced their proteid. The extraordinary effects on their working power are described elsewhere.¹⁰ To what extent such "natural eating" can help in pathologic cases has not yet been shown, although some physicians are reported to have found it a very valuable aid in their practice. Certainly it could scarcely fail to be more serviceable than the unintelligent and reckless diet prescriptions so often made.

Whether or not diet prescriptions are given, the actual diet employed by patients should receive study. This study is made easy by means of the graphic and mechanical methods.¹¹ These methods may be used with advantage in the kitchen by housewives desirous of supplying balanced meals, and may be of special service in institutions where it is important to provide complete and well-proportioned nourishment at a minimum of cost. On the mechanical diet indicator the weighted pins may be placed to indicate any proposed meal, and this meal, by a slight adjustment of the weights, may be balanced as exactly as desired.

The accompanying table of foods is classified under several heads

Cooked meats	Uncooked meats
Vegetables	Dairy products
Fruits	Nuts
Sweets and pickles	Cereals
Cakes, pastry, puddings and desserts	
Miscellaneous	

APPENDIX

The preceding table gives the data for the ordinary foods in a form most readily used for the graphic or the mechanical

⁹ Hutchinson, Robert. General Considerations on the Therapeutic Uses of Diet. Practitioner April 1906 p. 470.

¹⁰ For a short abstract see Science Nov. 16 1906. A full report will appear in the Transactions of the Connecticut Academy of Arts and Sciences.

¹¹ There is no patent on this device. Anyone is free to make and use it. The Battle Creek Sanitarium has had experience in constructing the apparatus. A regular instrument maker may take up its manufacture later if conditions warrant.

method The figures for carbohydrate are included, although, as has been shown, they do not need to be used in practical application, the location of each food on the "food map" being completely determined by its "latitude" and "longitude," i. e., the proportion of the fuel value in proteid and fat respectively. The foods, so far as possible, are prepared foods such as are served on the table, but unfortunately, the main sources of information being *Bulletin No 28* of the Department of Agriculture, for food materials it has not been possible to include all prepared dishes desired. Moreover, recipes vary so that it would be impracticable to supply data for such dishes which could be used with advantage or certainty. It is easily possible, however, for any one who uses the table to add to it the necessary data for any made dish of known recipe. All that is necessary is to translate the weights of the various ingredients into a number of "standard portions," and then to locate these ingredients on the "food map" and find their center of gravity. This will indicate the position of the composite food. The weight of a "standard portion" of this food is found by dividing the aggregate weight of all the ingredients used by the number of "portions" in them, as above ascertained.

Thus, to locate sponge cake, when the recipe is 3 eggs, 1 "cup" (4 oz.) sugar, and 1 "cup" (4 oz.) flour, the eggs, if of ordinary size, weigh $4\frac{1}{4}$ oz. and constitute, as the table shows, 2 "portions," the sugar, weighing 4 oz., constitutes 4.65 "portions" and the flour, weighing 4 oz., 4.2 "portions." This gives a total weight of $12\frac{1}{4}$ oz., and 11 as the total number of "portions." Dividing the former by the latter, we have 1.1 or as the weight of a "portion" of sponge cake. The position on the "food map" of sponge cake is now found by putting the pins at the points on the map as indicated by the table for sugar, eggs and flour. These weights, representing respectively 4.65, 2, and 4.2 "portions" the center of gravity shows the position of sponge cake, which is about 11 per cent of proteid and about 12 per cent of fat. This result does not agree exactly with sponge cake as given in the table, owing to the difference in recipe, that in the table probably including shortening.

Unless great precision is required, a sufficient approximation may be obtained in general by omitting fractional portions; thus, we may call the eggs 2 "portions," the sugar 5, and the flour 4. The resulting center of gravity may be found roughly by the eye, without even the aid of the diet indicator. It is surprising how close such a rough approximation will usually be found to the true value, as the influence of the errors in the particular ingredients, on the combined result, is small, and the various errors usually tend to offset each other.

Should the reader desire to add other items to the table, either of food materials or food stuffs he may do so by using the sources from which the table is constructed. Thus, if he will obtain from the Department of Agriculture *Bulletin No 28* "Chemical Composition of American Food Materials," he may translate the figures there given into the form to be entered in the table as follows. The weight in ounces of a "standard portion" is found by dividing 1,600 by the number of calories per pound given in the table. The calories per cent of proteid is found by multiplying the figure in the *Bulletin* table giving the weight per cent of proteid, by 1860 and dividing the result by the figure giving the number of calories per pound. The same calculation and the same factor, 1860, apply to carbohydrate. For fat the same calculation applies, but with the substitution of the factor 4220 in place of 1860. The three results may be verified by adding the resulting figures for proteid, fat and carbohydrate, the sum of which should be 100 per cent. To weigh foods better scales will usually suffice, the food being weighed in dishes and the weight of the dishes subtracted.

Abuse of Medical Charity—Is it presumption on our part to ask the trustees to protect the hospital physician from wasting his strength time and skill his capital in life on those who have no right to them? And furthermore to ask them to show due consideration to the family physician by refusing to allow well to do people to obtain free treatment at the institutions under their charge?—G. W. Gay, Boston

MYXEDEMA.

CAMPBELL P. HOWARD, M.D.
Outdoor Physician to the Montreal General Hospital.
MONTREAL, CANADA

(Continued from page 1230)

CASE 4—White, female, aged 46, multipara pronounced clinical picture, six years' duration, thyroid therapy, loss of $21\frac{1}{2}$ pounds in eight weeks, recovery.

Patient—F. A. American, housewife, Nova Scotia, Canada was admitted to the Johns Hopkins Hospital March 16, 1895, complaining of "swelling and apathy."

History—Family and personal history were unimportant. Patient was married and the mother of several children. In her youth she had been a very beautiful woman, and always very active in family and social duties.

Present Illness—This began insidiously about five or six years before admission, when the patient was about 40 years old, and progressed steadily until it resulted in almost complete physical and mental disability. The face became bloated, the eyeballs being especially full and bagggy. Enormous pads developed above the clavicles. Her hands and feet gradually enlarged, and the skin everywhere was unusually harsh and dry. Her hair fell out and she became abnormally sensitive to cold. She was dull and apathetic, but hypersensitive on one point her looks. She exhibited a dislike for society, and at one time refused to see even the members of her own family. Dr. Osler, who knew her in her youth, at his first visit "could scarcely believe that the bloated shapeless mass of humanity had twenty years ago been the belle of her town."

Physical Examination—Examination on March 18, 1895 revealed a characteristic edematous facies, forehead was much swollen and infiltrated but the wrinkles were not obliterated. Both eyelids were infiltrated and edematous, and there were bags of edema in the lower lids. The palpebral orifices were distinctly narrowed. The cheeks looked swollen, and the features were coarse. The movements of the facial and ocular muscles were good. Pupils were active, lips chapped. The tongue was clean, smooth and swollen. There was a distinct swelling above both clavicles and at the back of the neck. The hands were puffy and swollen (though this varied a good deal), and the skin was glazed and cracked.

The skin was universally dry and harsh. The teeth were loose, several were lost and the gums had receded. The hair which was formerly very abundant, was very thin, and over the scalp there were several irregular bald patches. There was a marked depression, somewhat V shaped, in the anterior triangle of the neck, and no thyroid gland could be felt. The intelligence was good. She was somewhat emotional, but had no delusions. Cerebration was slow.

The voice had become harsh and rough. The pulse was from 80 to 88 to the minute. The temperature was subnormal 96.5 to 97.8 degrees. The weight was 158 pounds. The urine varied from 650 to 890 c.c. in twenty four hours specific gravity of 1008 to 1015, and contained a trace of albumin, but no casts.

Clinical History—March 20, 1895. Thyroid extract, gr. i., t. i. d.

March 22. There was sweating of the palms of hands and also burning pains in the limbs. She was very despondent.

March 28. The pulse gradually increased in rate averaging 95 to minute. The puffiness of the face was greatly diminished and there was no longer edema about the lids. She was much brighter and showed an interest in her surroundings.

April 1. The temperature was often above normal and the pulse rarely below 100.

April 4. She had lost 12 pounds in two weeks and then weighed 146 pounds. The physical and mental improvement continued steadily.

May 11. She was discharged having further improved and having lost in all $21\frac{1}{2}$ pounds in weight ($136\frac{1}{2}$ pounds) in the eight weeks following the administration of about 257 grains of thyroid extract. She was cheerful the swelling and puffiness had all gone and she was an entirely different woman. The amount of urine had increased after commencing the extract and often reached 1,000 to 1,200 c.c. Subsequent to her

discharge from the hospital Dr Osler heard on several occasions that she had remained perfectly well, was bright and alert, and engaging actively in her former social and home duties. She still, however, was using at intervals the thyroid extract.

CASE 5—White, female, aged 39, tripara, typical picture, four years' duration, thyroid therapy, loss of 24½ pounds, recovery.

Patient—W A, American, housewife, of Alabama, was admitted to the Johns Hopkins Hospital Feb 20, 1906, complaining of "swelling of various parts of the body."

History—Family history was negative for goiter or myxedema. Patient had measles and whooping cough once each and pneumonia twice in childhood. She also had malaria in childhood and again at her thirty-fourth year. At her fourth or fifth year she had a swelling in the right side of her neck which finally broke down and discharged, leaving a cicatrix (tuberculous adenitis?). Menses were regular from fourteenth year to present illness. She had three children, the youngest of whom was 12, no miscarriages. She had swelling of her feet since birth of her first child, nineteen years before admission.

Present Illness—Though for many years she had noticed "bloating of the feet," it only became pronounced when she was 35 years old, i e, four years before admission. She thought that formerly the swelling occurred only in the spring time. This edema spread from the feet to the hands and eyelids. The eyelids were especially puffed in the morning. The skin was harsh and dry. At times the lips and tongue became so thick that she could hardly speak. The mind had been dull of late. The feet were constantly tired. Numbness and muscular cramps were all over the body. She was often very nervous. The menses became irregular and from her thirty-second year occurred only about once a year, she had not menstruated at all during the year before admission. The appetite was poor and the bowels were constipated. She got up once or twice each night to micturate.

Physical Examination—Examination on Feb 21, 1906, revealed a large framed woman of good color. There was marked pinkness of the cheeks in contrast to the excessive pallor about the eyes. The skin was extremely harsh and dry. There was a very marked puffy and edematous appearance of the face (especially about the eyes), the hands and also in the supraclavicular regions. The feet and legs gave the appearance of an enormous edema, but there was no pitting. The subcutaneous tissue had a peculiar resistant feeling.

The tongue was clean. The condition of the thyroid was not noted. The abdomen was full, but both the abdominal and thoracic viscera seemed normal. The pulse varied from 60 to 68 to the minute. The temperature was subnormal, 98.8 to 98 degrees. The weight was 240 pounds. The urine was 800 to 1,000 c.c. in twenty-four hours, sp gr, 1.016 to 1.020. It contained a faint trace of albumin on several examinations, but once only a few granular casts.

The blood examination revealed Hb, 70 per cent, red blood corpuscles, 4,232,000, white blood corpuscles, 3,600. The differential count was about normal, thus:

	Per cent
Polymorphonuclear neutrophils	70.5
Small mononuclears	17.5
Large mononuclears	9.5
Mastzellen	1.5
Eosinophiles	1.0

Clinical History—March 3 1906. She was given thyroid extract gr ss, t.i.d., which was increased to gr ¾, t.i.d., on March 5.

March 7. There was a decided improvement in the condition of the skin of her hands, which was thinner and looser. The pulse rate was increased.

March 9. The patient had lost 10 pounds. She menstruated for the first time in one year. As, however, she was very nervous and hysterical, crying frequently and complaining of headache and pains in her back and limbs, the thyroid extract was omitted for twenty-four hours.

April 16. The improvement continued, the puffiness of the face and extremities disappearing, the facies losing their former dull apathy and the voice becoming natural. The pulse

rate also gradually increased to 88 to 100 for the minute, though there was little or no change in temperature. The hemoglobin rose to 80 per cent and the red blood corpuscles to 4,400,000. The quantity of urine showed no great difference, though occasionally amounted to 1,300 or 1,400 c.c. She was discharged, having taken 100 grains of thyroid extract and having lost 24½ pounds (215½ pounds) in eight weeks.

Subsequent History—Oct. 6, 1905. A letter on this date from the patient stated that since discharge from the hospital her "general health had been very good," and she then weighed 170 pounds (i e, a loss of an additional 45½ pounds). On one or two occasions she had slight returns of her previous affection, which, however, were relieved by the tablets, three of which she was using at the time of writing.

CASE 6—White, female, aged 38, tripara, case of moderate severity, five years' duration, thyroid therapy, loss of 4 pounds in 16 days, recovery.

Patient—M W, American, housewife of North Carolina, was admitted to the Johns Hopkins Hospital, Feb 17, 1903, complaining of "swelling of the body."

History—Mother alive, but has symptoms resembling those of the patient. Maternal grandmother and uncle died of "kidney trouble." Patient had whooping cough in childhood and measles at 22. The menses were regular until the present illness. Was married and had three children, the youngest 7 years old. No miscarriages. Average weight, 140 pounds.

Present Illness—Began at her 33rd year (1898) with a gradually developing swelling and puffiness of the skin, which was of general distribution and more marked at night than in the morning. The complexion became pale, sallow and yellow. Giddiness developed at the onset and persisted. It was present sometimes for half a day at a time, even when she assumed the recumbent posture. At first this giddiness occurred only two or three times a year, but has recently become much more frequent. Indigestion developed in 1901, but was uncomplicated by nausea or vomiting. The appetite was good. The bowels had been very constipated except for an attack of "dysentery" in 1901 and again in May, 1902, since which she steadily grew more edematous, especially about the eyes. She had constant "buzzing in her head" since October, 1902. The eye balls became painful and very sensitive, and there were neuralgic pains in the back and legs. Weakness and dyspnea on exertion developed and gradually increased. The menses became irregular and scanty in 1901, but more recently became very profuse and the flow almost continuous.

Physical Examination—Examination on Feb 18, 1903, revealed a striking appearance. The face was swollen and had a curious puffy edematous character, especially about the eyes. Cerebration and speech were slow. There was slight puffiness of both hands and feet. The skin was harsh and dry and more or less sallow in color. There was no enlargement of the thyroid gland. The tongue was clean. The abdomen was slightly full and the bands of the ascending and descending colon were readily felt. The heart and lungs were normal. The pulse was rather small, 72 to 76 to the minute. Temperature was subnormal, 98.8 to 98.4 degrees. Weight was 138½ pounds.

The blood count showed Hb, 62 per cent, red blood corpuscles 3,736,000, white blood corpuscles, 6,700. The urine varied from 540 to 840 c.c. in twenty-four hours, sp gr 1.016, trace of albumin and an occasional hyaline cast.

Clinical History—Feb 20, 1903. Thyroid extract, gr v, t.i.d.

March 6. The tonsils were enlarged and the fauces were injected. The temperature rose to 99.2.

March 8. The temperature gradually reached normal, but the pulse rate was practically unaltered. She had lost 4 pounds during sixteen days.

March 15. The amount of urine showed a decided increase from the day after beginning the thyroid extract, averaging about 1,500 c.c. in the twenty-four hours, but occasionally reaching 1,600 to 1,700 c.c.

The patient was discharged, practically well, after having taken 345 grains of thyroid extract in the twenty-three days, and having lost further in weight.

CASE 7—White, male, aged 51 married twice, symptoms of moderate severity, six months' duration, thyroid therapy, loss of 4 pounds in six days recovery

Patient—A. M., Canadian, merchant of Quebec, was admitted to Johns Hopkins Hospital Nov. 29, 1903, complaining of "buzzing in head," "swelling of arms and hands," "coldness and numbness of feet," "catarrhal diarrhea."

History—Family history was negative. Patient had measles and scarlatina in childhood, and neurasthenia in 1899. He had worked hard and constantly for years. His habits were good. He had married twice and had five children by first wife and none by second. His pulse had been slow for years, but never irregular before the present illness. The bowels were regular. His average weight was 185 to 190 pounds.

Present Illness—In January, 1903, he first suffered from an attack of "catarrhal diarrhea," which had recurred at intervals. On July 1, after exposure to a hot sun while fishing, he first noticed a "buzzing sensation in the head like the sound of rapids." At the same time there was a sense of heaviness in the hands. On July 10 he noticed swelling of the face about the eyes. Three to four weeks later he suffered from cold and numbness of the hands and feet, which were slightly swollen. The swelling became more marked on the upper extremities as far as the shoulder joints. The skin of the hands and face was harsh, dry and inelastic. The voice became husky and "throaty," and the speech slow. There was constantly a peculiar flavor in the mouth. As the sclerotics and skin had a somewhat yellow tinge, he was treated for catarrhal jaundice. There was at times a sense of fullness below the heart with periods of intermittent action of the heart. He had great difficulty in keeping himself warm, requiring a heavy undershirt and a hot water bottle at night. He had not attended to business since August 1903, because of a disinclination for work and not because of any slowness of cerebration or loss of memory. He had consulted several physicians, who had always found his urine clear.

Physical Examination—Examination by Dr. Osler on Nov. 27, 1903 (two days before admission) revealed a well nourished man 5 feet 11 inches in height. The face was sallow, yellowish and waxy, and looked a little swollen. The eyelids were puffy and edematous as well as the skin above them. There was no special swelling of the ears. The skin was a little dry and hard. The hands were unusually dry, a little bluish and distinctly swollen. He thought that his right arm was a little swollen. The general surface of the skin of the body was unchanged except that it was a little dry and harsh. The pad above the left axilla was larger than above the right. His voice was husky. There was flattening in front of the trachea and no thyroid gland could be felt. The spleen and liver were both just palpable. There was no enlargement of the lymphatic glands. Cerebration was slow.

Nov. 29. On the day of admission, in addition to the above data, it was noticed that his expression was dull and facies heavy. The hair seemed normal. The gait was slow and he was deliberate in all his actions. The pulse was slow (45 to 52 to the minute), blood pressure was 100 to 110 mm. Hg., the radial artery was sclerosed.

The temperature was subnormal, 97 to 98 degrees.

The blood showed Hb. 70 per cent., red blood corpuscles, 4,104,000; white blood corpuscles, 7,800.

The quantity of urine before treatment was 620 cc. in twenty-four hours, the sp. gr., 1.011, and it contained neither albumin nor sugar, but a few hyaline casts.

Clinical History—Dec. 1, 1903. Weight, 172 pounds. He was given thyroid extract gr. v, t. i. d.

December 5. The amount of urine increased immediately after thyroid extract to 2,110 cc. in the first twenty-four hours, to 4,025 cc. in the second twenty-four hours. It always remained above 1,000 cc.

December 6. The patient was discharged very much improved after having taken 90 gr. of thyroid extract, and having lost 4 pounds in the six days (168 pounds).

December 16. He returned to see Dr. Osler, who noted "a remarkable change in appearance, all the infiltration had gone from his face and ears, though he still looked a little sallow. The face was no longer dry and the hands were not nearly so

dry and not at all rough. The stomach was very much out of sorts, though the tongue was clean. The pulse was S2 to the minute.

Jan. 20, 1904. A letter from him stated that he continued to improve with the use of thyroid extract. His weight was 170 pounds.

Oct. 26, 1905. A letter on this date states that although he had not his former vim he was very well. He weighed 180 pounds without clothes. He had occasionally trouble with his bowels. He was taking daily one tablet of 5 gr.

CASE 8—White, female, aged 44, decipara, atypical case, thyroid therapy, improvement, edema never entirely disappeared.

Patient—A. F. L., American, no occupation, of Baltimore, consulted Dr. Osler Feb. 28, 1895, and complained of "swelling of the lip and face."

History—Father died of "heart disease" otherwise family history was negative. Patient had always enjoyed excellent health. She had been married twenty-three years, and had ten children, six of whom were living. Ever since maturity there was a tendency to swelling of the feet, particularly at night.

Present Illness—For a year or more before consulting Dr. Osler she had been getting pale. In August, 1894, she noticed that her feet and ankles were swollen, the left much more than the right, and more recently the left hand had seemed a little puffy. The legs were more swollen at night than in the morning. The face had been a little swollen and flabby for several months and the eyelids became edematous in the morning. She thought that she had gained slightly in weight. She did not complain of any susceptibility to the cold. She still perspired. For some time she had been very low spirited and despondent. In August, 1894, she had a rectal abscess, which, however, left no fistula.

Physical Examination—She had a pale yellow, very muddy complexion, the skin was dry, but there was no great puffiness of the eyelids nor had she the broad features so characteristic of myxedema. There were no folds of skin on the forehead, which showed a little brownish discoloration. The skin of the backs of the hands was dry and not especially puffy, but she stated that on the morning of examination the left hand was swollen. The neck was not swollen, there were no large supraclavicular pads. The thyroid gland could be felt. The legs were swollen particularly below the calves. The circumference at the ankle was almost the same as in the upper part of the leg. The swelling was particularly marked about the malleoli. There was no pitting on pressure. There was no change in the voice. The pulse was 70 and not of increased tension. The temperature was 98.5 degrees. There was no optic neuritis or retinitis. The urine was not increased in amount, sp. gr. 1.017, and always contained a trace of albumin, but no tube casts.

Clinical History—April, 10, 1895. The patient had taken thyroid extract gr. iii, t. i. d., for a month, before any change was noted.

June 15. The dose of the extract was gradually increased until she took gr. v, t. i. d. The legs became softer, less swollen and very much smaller. She became thinner, the appetite was better, the dryness of the skin disappeared and she was in very much better spirits.

December 17. She was then taking gr. xv, t. i. d. Her physician, Dr. A. F. Morris, wrote that "her intellect is not at all dull, and she is full of energy and she says she feels stronger than she did." The legs swell, however, on cessation of the drug. Her limbs felt heavy and her feet warm and tingling. There was also some swelling above the clavicles and over the abdomen.

Sept. 27, 1905. Her physician again reported that the patient was enjoying good health except for a severe lobar pneumonia in the winter of 1903 from which she made a good recovery. There was still some edema of the limbs, yet not enough to trouble her. Some time ago she had discontinued the use of the thyroid extract, after having taken it regularly for some years.

CASE 9—White female, aged 55, multipara, typical case, duration probably six to seven years, thyroid therapy, recovery.

Patient—J K P II, American, no occupation, of Tennessee, consulted Dr Osler Sept 16, 1897, and complained of weakness and swelling of face and extremities.

History—No family history of goiter, myxedema or any neurosis.

Patient had always enjoyed good health, had been married thirty one years, and had five children, all of whom were girls.

Present Illness—She first noticed six or seven years before, weakness and tingling over the body, but chiefly on the left side. She then suffered from "sick spells" during which her color became yellow brown, and there was numbness, weakness, and prostration. She next began to suffer with palpitation of the heart and feebleness and weakness became constant. During her fifty fourth year (1896) she first noticed swelling of the face and extremities, though since 1890 or 1891 the face had looked "greasy and thick." On account of the latter one physician had treated her for erysipelas for six months. Later, the body became very much swollen, there was never diarrhea or uterine hemorrhage. For three months before consulting Dr Osler she had taken thyroid extract, gr v, t.i.d., with marked benefit.

Physical Examination—Examination on Sept 16, 1897, revealed an elderly woman with a very yellow anemic color. The face was not specially moon shaped or infiltrated, though there was still a little fairly characteristic infiltration about the cheeks. The forehead showed remains of the former tension of the skin and she was unable to pucker up the forehead. There was no special pigmentation of the face. The tongue was clean. The neck was large and dark in color. The trachea was easily felt, but the thyroid was not palpable. There was no longer any infiltration over the trunk. The hands were a little suggestive, the skin being rather relaxed. There was marked infiltration of the skin of the left arm, while the dorsum of the left hand was also somewhat infiltrated. Further, on the palm of the left hand over the head of the metacarpal bone and first phalanx of the index finger, the skin was remarkably infiltrated and swollen and she could not close the left hand well. The ankles were a little infiltrated, but did not pit on pressure. There was a remarkable degree of infiltration of the abdominal wall. There were no signs of any diffuse scleroderma.

Subsequent History—Jan 19, 1898. Her physician, Dr C P Fox, reported that the patient was almost well.

Oct 16, 1905. Her physician, Dr C P Fox, wrote that she was in fair health, somewhat anemic, but showing no symptoms of myxedema except a slight scleroderma, principally about the hands and terminal phalanges. Temperature was normal and voice clear. Hair rather thin and dead looking. Mental faculties clear and memory good. Digestion regular. Urine has not contained any albumin. At one time she was troubled with an "irritable heart" due to excessive use of the thyroid tablets (gr x, t.i.d.). She now takes gr v, t.i.d.

CASE 10—White, female, aged 29, primipara, typical case, duration two years. thyroid therapy, loss of 40 pounds in eight months, recovery.

Patient—M L A. American, no occupation, of New York City, consulted Dr Osler Dec 2 1904, and complained of "swelling all over the body."

History—Family history was negative except for the fact that her father and mother were first cousins. Patient had no serious illness until her twentieth year, when she had a severe attack of typhoid fever. She married at 21 and had one child, now 8 years old.

Present Illness—This dated back two years. She rapidly became stout and within a year rose from 130 to 185 pounds. There were puff swellings all over the body. There was one on the back of the neck which gradually disappeared. The hands became so swollen that it necessitated the filing off of her rings. Her feet became so swollen that she could not get her shoes on. The swelling of the body often prevented her wearing her corsets. Her hair fell out. She was always cold and could never get warm. She felt better in warm weather. She was always tired and had no ambition or interest in anything. At times she felt restless. She became absent minded and as often very melancholy. The menses were irregular and scanty. A diagnosis of myxedema was made by her physician, Dr Edgar

Smith and she commenced thyroid extract, gr v, q d, in March, 1904, since which time the edema diminished and she lost nearly 40 pounds (weighing in December but 137 pounds). She consulted Dr Osler chiefly for the mental depression and absent mindedness.

Physical Examination.—Examination revealed a healthy looking woman. The facies were no longer myxedematous. There was plenty of hair. There was neither pallor or pastiness of the complexion. There was, perhaps, a little puffiness about the eyes. She seemed bright and active. There were no pads above the clavicles. The neck was not full. The outlines of the sternomastoid and sternothyroid muscles were very marked. There was a distinct groove between the thyroid cartilage and the latter. No definite thyroid gland was palpable. There was no special puffiness of the hands, which felt warm, though she complained of being cold. Over the hips there was still a little puffiness and the skin was a little lax, but did not pit. Skin was nowhere dry. The heart sounds were clear, and the pulse regular and of good volume. A letter to the patient in October, 1905, was not answered.

AMERICAN SERIES

I have collected from American literature from 1881 to July 1, 1905, 92 undoubted cases of myxedema. Some few others were not accepted owing to an insufficiency of the data or a probable error in the diagnosis. Many cases reported as myxedema were examples of cretinism, which with operative myxedema are not included in the analysis. Two of my 10 cases had been previously reported, so that the entire American series includes 100 cases. The latter I intend to analyze for comparison with the other published series.

RACE

By far the great majority of cases occurs in the white race. It is usually stated that "no cases have been recorded in the colored race," yet in America, E E Maxey,¹⁹ in 1895, reported a typical case in a negress. H J Berkely,²⁰ in 1897, reported 8 instances of localized myxedema-like deposits in the scalp of 8 colored patients in Baltimore. As the latter were not instances of true myxedema, only Maxey's case was included in my series. Hence there was an incidence of but 1 per cent in the colored race. More recently (1905), instances of the disease in the natives of British India have been reported by Hamilton, Hope and Smith.²¹

NATIONALITY AND LOCALITY

Myxedema occurs most frequently in cold climates, and is probably more frequent in Europe than in any other continent. Of the European countries, Great Britain produces the majority of the cases. In England it is more prevalent in the north and especially in the lower banks of the Tyne valley. It seems to be still more common in Edinburgh and Dundee in Scotland. The London committee found that of 76 cases, 26 were from England, 5 from Scotland, 2 from Ireland and 15 from France, of which 11 were from lower Brittany. In Germany and France the disease is rare. Of my series of 100 cases, 16 patients were stated to be of foreign birth (English 5, Scotch 3, Irish 2, German 3, Austrian 1, Polish 1, Italian 1). Of the remaining 84, 19 were stated to be American-born and an absence of note to the contrary in the other 65 may lead one to assume that they were also of American birth. Hence 84 per cent of my series were presumably born in America.

As to the distribution of the disease in America, the data are rather inadequate. In only 31 cases was the

¹⁹ Med Sentinel Portland Ore 1895 III

²⁰ Am Jour Insanity 1897 98 II

²¹ Indian Med Gaz. Calcutta, 1905 xl.

locality definitely stated. Of these one patient had developed the disease in England and another in Poland. Of the remaining 29, 11 were reported from Canada or the northeastern states (Ontario 2, Quebec 2, Nova Scotia 2, Vermont 1, Massachusetts 1 and New York 3), 4 from the Middle West (Michigan 2, Wisconsin 1, Indiana 1), from the West (California 2, Colorado 2, Kansas 1, Idaho 1), and 8 from the South (Maryland 3, Virginia 2, North Carolina 1, Tennessee 1, Alabama 1). In 69 other cases though the locality of the patient was not stated, that of the physician may give some clue. In the group 56 cases were reported by northern physicians, 10 by western and 3 by southern.

Hence it would appear from a study of both of these groups that in America, myxedema is widely distributed, though apparently more prevalent in the northeastern districts. I say apparently, for one must allow for the greater population and the greater facility for observation and publication in the northeast. It is of interest to note that Dock is quoted by Messinger²² as having commented on the rarity of myxedema in Michigan, although other diseases of the thyroid gland are common there.

Since I began the study of my cases H. C. Moffitt has stated that he believes that diseases of the thyroid gland are more common in California than in many other states in America. He collected 83 cases from California, of which 53 were from San Francisco. He found myxedema was more common in the "bay counties" of California which, however, were the most densely populated.

SEX, AGE AND SOCIAL STATUS

It has long been recognized that females are more prone to the disease than males. The London committee collected 94 females to 15 males (6 to 1). In 150 cases, Hun and Prudden¹⁰ found 113 females, 32 males and in 5 the sex was not stated (3.5 to 1). In 370 cases Murray gave a much higher proportion, viz., 322 women to 48 men (7 to 1). In my series there were 86 women, 13 men, and one case in which the sex was not stated (6.6 to 1).

As to age it has been found that no period of life, from infancy to extreme old age, is exempt. The cases before puberty do not interest us here. The London committee found that the first symptom of the disease manifested itself in the third to fifth decade in 49 of 84 cases.

Hun and Prudden's¹⁰ tables (which unfortunately include cretins) show that the average age at onset was 38 years in 76 women, and 42 years in 20 men. In 274 cases Murray found that the disease developed between the fortieth and forty-fifth year in women and from the thirty-fifth to the fiftieth year in men. My table shows the preponderance of both sexes in the fourth and fifth decades. In one male the disease first appeared at the advanced age of 68 years. In 12 females the age at onset was between 50 and 60 years, and there was no patient over 60. On the other hand in a large proportion of females (13 of 87 females or 15 per cent) the disease occurred between 20 and 30 years in contrast to an incidence among the males for the same decade of 1 out of 13 cases or 7.6 per cent. Hence we may say that the disease is relatively more frequent in women from 30 to 60 and in men from 30 to 50.

Decade	Males	Females	Total
15-20 years	1	1	2
20-30 years	1	13	14
30-40 years	4	26	30
40-50 years	4	20	33
50-60 years	1	12	13
60-70 years	1		1
Not stated	1	6	7
Grand total	13	87	100

The social condition plays but a minor role as an etiologic factor. The London committee thought that the lower classes were most prone. In the American series the status of the patient was usually not given, yet it is interesting to remark that 9 of the 10 cases from this clinic were treated in the private wards.

FAMILY ANTECEDENTS AND INFILTRITY

Unquestionably there is a thyropathic tendency in certain families. In other words the disease may be transmitted directly from either parent, but more commonly from the mother. Again several members of the same generation may be attacked. Thus in the London series in 2 of the recorded cases the patients were sisters, in 2 they were relatives, while in one the father and in another the mother in all probability died of the disease. In other words there is a family history in 6.6 per cent. Hun and Prudden refer to one family in which 3 sisters had myxedema, one of whom had a daughter with the disease. Altogether they had 9 cases (16 per cent) with a family history of myxedema and there was direct transmission in 8 per cent.

In my series some mention is made of the family history in 68 cases. Of these 8 had a history of myxedema in the family (11.8 per cent.), which, however, includes 2 of Hun and Prudden's¹⁰ cases. Exclusive of the two latter, one woman had a brother die from myxedema and one sister living with slight myxedema. In another case a woman had an aunt and a cousin with pronounced myxedema. Another woman had a sister with myxedema, still another with a myxedematous mother, while the patients in cases 1 and 2 of my personal series were sisters, who had a third sister die with exophthalmic goiter. In the American series there was another woman whose mother presumably had myxedema. It is possible that consanguinity in the parents may predispose to myxedema. There are practically no statements as to this factor in the reported cases, but in the two cases in which this point was inquired into in my personal series it was found that in Case 3 the parents were second cousins while the grandparents were first cousins and in Case 10 the parents were first cousins. It would be interesting to get more data on this question. The London committee also include neuroses and tuberculosis as predisposing causes. Thus in 12 of their series of 16 per cent, in 13 cases or 25 per cent of Hun and Prudden's¹⁰ and in 8 cases or 11.8 per cent of my series there was history of insanity or other neurosis. As to tuberculosis there was a history of phthisis in the near relatives of 20 patients (25 per cent) of the London cases, in 9 (17 per cent) of Hun and Prudden's¹⁰ and in 10 (11.7 per cent) of my series.

PERSONAL ANTECEDENTS

The usual antecedents of chronic maladies viz. alcohol and syphilis, play little or no part. In the London series there was a history of syphilis in 6 and of intemperance in but 8 of the cases. Hun and Prudden¹⁰ found a history of syphilis in 3 while in my American series there was a history of syphilis and alcohol in 2 cases each. In women myxedema bears some relation to the marital state. Of 81 cases in which this point is noted only 10 of the patients were married. In the London

2. Trans Mich Med Soc. 1894 xviii

rapid child-bearing, according to most authorities seems an important predisposing factor. In the Hun and Prudden¹⁰ series of 64 cases in which a statement is made in regard to the number of pregnancies, 4 patients were nulliparæ and the other 60 were multiparæ, having borne on an average 5 children. In the London series 62 of the 69 patients were married women who had borne children and 14 were single, 16 had given birth to 8 or 9 children each. Of the 71 married women in my series there is no statement as to the number of children in 22, of the remaining 49, 6 were nulliparæ, 3 had one miscarriage each, while 40 had one or more children with an average of about 5 children each. Fourteen women had six or more children, two of whom had 12 each. Five of my series and 15 of that of Hun and Prudden¹⁰ dated the onset of myxedema from their last pregnancy. In 6 of Hun and Prudden's and in one of my series the onset occurred directly after a severe puerperal hemorrhage. It has been suggested that the menopause may also play some part. In only three of Hun and Prudden's cases, and in but one in my series was it definitely stated that the disease commenced at the menopause, although in a number of other cases it occurred about that time. Thus in 7 of my series the menopause preceded the onset of the disease. As myxedema is most frequent in women between the ages 49 and 45 the usual age for the menopause, atrophy of the thyroid gland and with it myxedema may have some fairly constant relation to changes in the menstrual function.

Of other possible, predisposing factors mental shock and worry must be considered. There was a history of this in 27 of Hun and Prudden's series and in 18 cases of mine. The acute infections, except in so far as they may be associated with or followed by a thyroiditis and subsequent atrophy, can be left out of reckoning. In one case there was a history of glandular inflammation of the neck with subsequent atrophy of the thyroid gland. In another case a severe attack of malarial fever just antedated the onset of symptoms. In short we may say that excessive child-bearing and mental shock and worry may play no inconsiderable rôle in the etiology.

RELATION OF GRAVES' DISEASE

I believe that a history of exophthalmic goiter preceding the onset of myxedema would be more frequently elicited if more careful inquiry were made. In three of the American series (of which one was Case 2 of my series) there was a definite history of Graves' disease preceding the onset of myxedema, 3, 10 and 14 years, respectively. Baldwin,²³ in 1895, reported 4 instances of myxedema following Graves' disease in from 2 to 5 years. Of further interest is a case reported in 1893 by Maude²⁴ of a woman with myxedema whose daughter had Graves' disease. Moffitt¹⁷ refers to a similar case. In my series two sisters (Cases 1 and 2) had myxedema one following exophthalmic goiter while a third sister has since suffered from exophthalmic goiter. Both myxedema and Graves' disease have a special hereditary tendency of their own. That of the former has been referred to under the family history. That of the latter may be illustrated by the fact that in 5 of 40 cases collected by MacKenzie there was a family history of the disease. Osterreicher reported the case of an hysterical woman who had 10 children 8 of whom had exophthalmic goiter one of whom in turn had 4 daughters with the same disease.

MORBID ANATOMY AND PATHOGENESIS

The morbid anatomy of this disease has been fairly well studied. In my American series there were 5 autopsies, all fairly completely reported.

THYROID GLAND

The thyroid gland, on the disease of which myxedema depends, is diminished in size and loses its dull reddish tint of health, becoming yellowish or pale. Occasionally the gland is increased in size, but in such cases is functionally inactive. A delicate fibrous tissue invades and replaces the proper glandular tissue. There is a small-celled infiltration of the walls of the vesicles, accompanied or shortly followed by epithelial proliferation in the vesicles themselves. Next the gland becomes converted into a delicate fibrous structure in which clumps of small round cells, evidently the remains of vesicles, are scattered. In the last stage the capsule is much thickened, while the parenchyma of the gland is made up almost entirely of fibrous tissue in which small islets of round cells are sparsely placed. There is also an end arteritis and periarteritis resulting in a diminution of the lumen of the vessels. Ord²⁵ writes

It appears to me that probably the atrophy of the gland productive of myxedema is frequently due to inflammatory destruction of the gland tissue.

The process is analogous to that in cirrhosis of the liver or kidney. There was atrophy of the gland in all five of the American postmortems.

SKIN

The skin on section yields no serous exudate, but remains unaffected and jelly-like. Histologically there is nuclear hyperplasia and development of connective tissue, both of which changes occur chiefly in the neighborhood of the sweat and sebaceous glands and around the hair follicles. The epidermis may be atrophied and the lymph channels dilated. Sometimes there is an unusual interval between the bundles of fibrous tissue of the corium as found in ordinary edema. There is usually an endarteritis of the cutaneous vessels, but the nerves are generally unaffected. In the sweat and sebaceous glands the epithelium becomes swollen and later the nuclei proliferate and the lumen of the tubule becomes occluded. The hair follicles are surrounded by fibrous tissue which sooner or later contracts and causes atrophy of the roots. These changes, then, account for the loss of the hair and the diminution or absence of the secretion of sweat and sebum.

NERVOUS SYSTEM

According to the Clinical Society's report, there is no important change in the central nervous system. Boyce and Beadles found a central endarteritis in one case of myxedema associated with insanity, and in addition a colloidal material in many of the vessels and perivascular spaces. Cushier²⁶ found thickening of the vessels of the spinal cord and atrophy of the cells of the anterior cornua in one case. The hypophysis cerebri was found enlarged in 2 cases of myxedema by Boyce and Beadles and in 1 case by Ramsey Hunt.²⁷ An explanation of the origin and mechanism of the production of the nervous manifestation has been sought for by various authors. Hadden⁸ believed them to be due to a contraction of all the peripheral lymphatics owing to a disturbance of cer-

tain centers seated probably in the medulla and acting through the sympathetic system Clouston²⁰ ventured the following hypothesis

The neuroglia of the cortex becomes to a slight degree water logged by mucin, which causes lowered anabolism and catabolism of the cells, whose reactiveness is thereby impaired

The majority of writers, however, ascribed the nervous symptoms to the padding of the peripheral nerve endings by the myxedematous deposits which so interfere with the transmission of the afferent impulses that the central structures suffer secondarily by virtue of the defective afferent conduction. The most modern conception is the toxic theory, according to which there is an absence of the thyroid secretion, which is either itself essential to metabolism or neutralizes otherwise toxic products of metabolism

HEART

The heart frequently shows hypertrophy of the left ventricle in association with a slight fibrosis in the kidneys. There is a remarkable discrepancy between the symptoms of cardiac insufficiency in myxedema and postmortem degeneration of the myocardium. Slight atheroma of the large vessels was found in more than half of the London series

KIDNEYS

The kidneys have been enlarged in some cases owing to the presence of large quantities of a transparent or faintly granular material which interferes with the renal tubules

CHEMICAL ANALYSIS

A chemical analysis of the tissues will reveal an increase in the amount of the mucin in the skin, connective tissue, tendons, etc., especially in the stage of marked tumefaction, though not to the same extent as was first maintained. Hun and Prudden¹⁰ found a normal amount of mucin in the skin in one instance, and they did not believe that the mucin is so invariably increased as to justify the name myxedema. In the later or atrophic stage there is no apparent excess of mucin. The excess of mucin results from the degeneration of the protoplasm of the epithelial cells, of the goblet cells of the mucous membrane and of the cells of the acini of mucous glands. The mucin forms a constituent part of the ground substance or stroma of the connective tissue in which the cells and fibers are buried. It is a muco-albuminous material of which one of the constituents is mucin, the other a proteid of the globulin class resembling the paraglobulin of the blood

SYMPTOMATOLOGY

ONSET

The onset, as a rule, is very insidious. Several months or even a year may elapse before the symptoms are definite. For this reason it is often difficult to determine the duration of the disease. In a few cases, especially in young adults, the symptoms develop rapidly and become marked in a few weeks. A case reported by Osler²⁰ is a good illustration of this. The disease in a man, 31 years old, ran an acute course of 5 months with myxedematous symptoms associated with tachycardia, glycosuria, melena, mania and death

The first symptom as a rule, is languor. The ordinary daily duties become an effort if not actually burdensome. Then a constant chilliness or perhaps merely a greater sensitiveness to cold than formerly

may be noticed. Slowness of motion and increase in bulk make their appearance. Hun and Prudden¹⁰ found that when the disease did not commence insidiously, it usually commenced with some nervous or cutaneous manifestation

SOLID EDEMA

This is the most characteristic symptom and that from which the disease derived its name. The edema is best developed in the loose subcutaneous tissues and is very slight where the skin is firmly adherent to the underlying structures. The edema has certain definite characteristics, it is solid and firm, does not pit on pressure, is not affected by gravitation, nor when pricked does it exude fluid unless a watery edema be also present. Hun and Prudden¹⁰ explain the absence of pitting in myxedema by the fact that the edema is confined to the superficial layers of the corium where the interspaces are so small and the interlacement of the fibers so fine that the fluid is not easily driven away by pressure

The swelling in the majority of cases is first detected in the face, though the London committee thought that the legs and feet were most frequently the primary seat of the swelling. Sooner or later the edema becomes general, with a consequent increase in the size and weight of the body. There was increase in both bulk and weight in 46 of 50 cases in the London series. In the American series there was a definite statement as to the weight in 30 cases, of which 27 showed an increase, 3 of 100 pounds or over, 3 of 50 pounds or over, 4 of 25 pounds or over, and only 1 under 25 pounds. In 16 cases no exact figures were given. In 3 cases there was some loss of weight. The edema may vary from time to time under differences of temperature, being greater in cold than in warm weather

The Face—The face is most frequently involved, thus in our series it was edematous in 91 cases, of which the eyelids alone were affected in six. In only one case was the face noted to be unaffected. The features are broad, puffy and coarse. The eyelids are sites of transparent swelling, often described as "translucent folds," with drooping of the upper lids, to overcome which the eyebrows are arched in a peculiar fashion. The nostrils are swollen and broadened. The lower lip is thickened, everted and livid. The mouth is widened transversely. There is also a well-defined hectic patch over the cheeks and nose in sharp contrast with the pallid orbital regions. There is great diminution in the mobility of the features, giving rise to a very characteristic facial expression. The latter may be best described as "heavy," "apathetic," mask-like, "stolid or cretinoid." The solid edema obliterates the special character of the individual features resulting in a strong family resemblance between all cases of myxedema. Ord¹ in 1898, truly remarks that "the total effect is that of a mask of sorrowful immobility." The effect of the edema of the face is so characteristic that once seen will never be mistaken for anything else and is as pathognomonic as the facies of cretinism. In my series there were the characteristic facies in 93 cases in 36 of which the hectic flush was also noted. In the great majority of the 93 cases the description was in identical terms and in only a few were such general terms as "cretinoid," "myxedematous," "mask-like," etc. used. The nose is considerably increased in circumference so that the ordinary collar feels uncomfortably tight. In 18 of my series it was enlarged in 2 cases of which the edema was

chiefly confined to the back of the neck, and in one of the latter it was so great as to tilt the chin forward on the sternum

On each side of the neck above the clavicles are large soft projections, of dough-like consistency, consisting partly of fat, altered connective tissue and possibly in part of veins. These supraclavicular pads are similar to those seen in cretinism. Hun and Prudden¹⁰ found them present in 90 per cent of their cases. They were noted only in 25 of my series, though their absence was commented on in but two others.

Hands, Feet, Etc.—The hands are uniformly affected, being broad, clumsy and "spade-like"—a term first suggested by Gull. The fingers are swollen and moved with difficulty. The hands alone were involved in 47 cases. In several cases the fingers were said to be clubbed, and in one case the finger points were described as enlarged. In another 27 cases the entire upper extremity was attacked, though usually the edema is most pronounced in the forearms. The feet and legs may be similarly affected, as was noted in 57 of the American series. Slight watery edema of the skin, though not uncommon, is usually transitory and when persistent is certainly accidental. Pitting of the leg was noted in 7 of the series and in another 20 its absence was commented on. The extremities, too, are usually cold, often purple and livid. The abdomen is not uncommonly swollen and pendulous (27 cases in my series), due of course, rather to infiltration of the walls than an actual ascites. The navel may protrude as it does in cretinism, though the low position of the navel is not the rule. The genitals are sometimes involved in the process (2 cases). The entire trunk may be the site of the firm edema (10 cases), and, in fact, the edema may be general over the entire body (13 cases). In addition, there may be localized areas of infiltration of considerable size. Thus in one case a large tumor was present in the middle of the thigh.

CUTANEOUS SYSTEM

The skin and its appendages show marked and characteristic alterations, which increase with the progress of the disease. The skin itself is most frequently involved, being abnormal in 95 of the 96 cases in my series (99 per cent). In 4 other cases no comment was made on the condition of the skin. It is usually dry and harsh to the touch, owing to the diminished activity of the sudoriferous and oftentimes the sebaceous glands. In fact, sweat may be entirely absent, as was the case in 27 per cent. of my series. Desquamation often occurs in the form of a fine powder over the face, trunk and extremities. Sometimes the skin is desquamated in larger flakes, or even almost entire casts of the fingers or hands. The latter is more commonly seen following thyroid therapy. In early or mild cases the skin may be moist, smooth and otherwise normal except for a little puffiness and loss of elasticity.

The color of the skin, more particularly of the face, is usually altered. It may be merely sallow, gray or more often yellow. The skin was noted as yellow in 13 of Hun and Prudden's¹⁰ series, as well as in 13 of mine (13.5 per cent.). This may be so deep as to be mistaken for actual jaundice (two cases). Areas of pigmentation are by no means infrequent, especially about the face and neck, as occurred in 12 cases in my series and in 5 in Hun and Prudden's. The areas may be small and deep yellow (chloasma) or they may be large and irregular and consist merely of a yellowish brown stain. In one of my series actual bronzing was noted. Warts and

moles were relatively frequent and occurred in 4 cases of my series and in 12 of Hun and Prudden's.

Various forms of rashes occur, as erythemata (2 cases), vesiculi (2 cases), urticariæ (2 cases) and herpes (1 case). More serious inflammatory conditions may develop, as ulcers (1 case) and phlegmonous erysipelas with gangrene (2 cases). Pruritus was present in one case without evidence of diabetes. Lineæ atrophicæ may be conspicuous. The hair is very commonly diseased, as was the case in 72 of 77 cases (93 per cent.) in my series. Hun and Prudden¹⁰ noted loss of hair in 86 per cent. The usual indications of defective nutrition of the hair may be present, namely, falling out, dryness and coarseness, brittleness, a loss of luster or change in color. More commonly the hair of the scalp, axillæ and pubes is affected, but the eyebrows and eyelashes may become very thin, or even be entirely lost. More rarely there is loss of hair of the entire trunk, extremities and chin. Sometimes a crop of lanugo-like hair will develop. The scalp itself is often dry, scurfy and brown with many cracks in the epidermis. The nails may also show defective nutrition. They were diseased in 32 of 37 cases (86 per cent.) in my series, in 21 of 44 of the London series (47 per cent.) and in 10 of 13 of Hun and Prudden's series (70 per cent.). They are usually brittle and ridged and longitudinally striated. They may be stunted, discolored or abnormally curved. In two of my series there was actual clubbing of the fingers. While more commonly the nails of the fingers alone are affected, those of both the fingers and the toes or even of the toes alone (3 cases) may be diseased.

TEETH AND MUCOUS MEMBRANES OF MOUTH

The teeth are frequently diseased. In 18 out of 20 cases (86 per cent.) of my series they were noted as either loose, brittle, carious or as having fallen out, while in Hun and Prudden's¹⁰ series they were loose or lost in 64 per cent and decayed or brittle in 28 per cent. The mucous membrane of the mouth and lips is frequently swollen and pale and very apt to be bitten during mastication. The lips are often enlarged (19 cases), everted and pendulous, and may be of a dark purplish or violet hue. More commonly the tongue is enlarged, swollen and hypertrophic (42 cases), often to such a degree as to interfere with speech. Rarely it protrudes from the mouth as in cretinism. It may appear anemic or more rarely purplish in color. The soft palate is sometimes swollen and will then hang down on the tongue, its mobility may be considerably impaired. The mucous membrane of the nose does not escape. One patient in my series consulted a rhinologist for nasal obstruction due to a myxedematous condition of the nose. The gums are often spongy and soft and recede from the teeth. They often bleed very easily and may be ulcerated. They were noted as abnormal in 18 of my series. With the involvement of the buccal mucous membrane there is frequently salivation (13 cases), more especially at night or when asleep. The saliva often runs out of the corners of the mouth, giving to the patient the facies of an idiot. Sometimes the mouth is very dry, with even total loss of the salivary secretion. Hun and Prudden¹⁰ found the mucous membrane of the mouth was swollen in 95 per cent and anemic in 47 per cent. The larynx also may be pale, swollen and edematous with separation of the cords and consequent hoarseness. The larynx was involved in 4 patients of my series, two of whom first consulted a laryngologist who in both instances made the diagnosis

of myxedema Hun and Prudden¹⁰ found anemia of the larynx in 70 per cent, swelling in 56 per cent. and lack of approximation of the cords in 56 per cent. The nasal mucous membrane may present a similar picture as the other mucous membrane (2 cases) The frequency of rhinorrhea or nasal discharge (6 cases) would suggest a more usual involvement of the nasal mucous membrane The conjunctivæ sometimes do not escape (3 cases) and lachrymation is not infrequent (5 cases)

(To be continued)

THE DIAGNOSIS AND TREATMENT OF MALARIAL FEVER

DOUGLAS VANDERHOOF, M.D.

Clinical Instructor in Practice of Medicine, Medical College of
Virginia.

RICHMOND, VA.

The object of this paper is to lay emphasis on the accurate diagnosis of malarial fever, to review at some length the various conditions often ascribed to an infection with the malarial parasite, and to consider some points in the therapeutics of this malady

DIAGNOSIS

Blood Examination.—By this means only can a positive statement as to the presence of the malarial organism be made The technic involved is certainly very simple and, as a rule, it is not a difficult matter to demonstrate the parasite in either the fresh preparation or in a blood film stained with any of the good eosin-methylene blue mixtures In this connection I should like to lay some stress on the importance of the careful examination of the fresh blood, which can be done very readily, provided a clean slide and coverslip be used and a very small drop of blood be taken, thus insuring a thin, well-spread field The pigmented forms are easily recognized and should not be confused with any structures found in normal blood The pigment granules are fine and dark-brown in color, while the granulations of the leucocytes are more or less refractile The eosinophilic granules are much larger, round and regular in outline and not as dark as the pigment in the parasites The plasmodium, of course, is regularly contained within the bodies of the red blood cells, although a few extracellular forms are often seen, due to the rupture of some of the cells in making the preparation It is not uncommon, however, especially in malaria, for the leucocytes to contain small particles of pigment which they have ingested by their phagocytic action Such cells should be recognized, of course, by their general structure, containing, besides the pigment, a nucleus and the refractile granulations The beginner may be somewhat misled by small clumps of platelets with radiating strands of fibrin, the so-called "granular masses of Schultze" but these do not resemble at all the hematozoa The crescents and ovoids of the estivo-autumnal fever are very characteristic and are readily recognized when seen but they do not appear in the peripheral circulation until the fifth to the seventh day of the disease The demonstration of the young hyaline forms, best found just after a chill is more difficult but in a tertian infection attention may often be drawn to a corpuscle containing the parasite by the fact that it is swollen and larger than those surrounding it The recognition of the hyaline forms is rendered uncertain except to the eyes of a well-trained observer by the occurrence of the endoglobular degenerations which are invariably present sooner or later, depending on the condition of the blood

and the mechanical insult offered the red blood cells in making the preparation

It is generally stated that the parasites are most easily found in stained films, and this is undoubtedly so if they are few in number, but this should not discount the general value of the examination of the fresh blood In stained specimens care must be taken not to confuse the platelets, which are usually numerous in malaria with parasites, especially when they are superimposed on red blood cells or are gathered into clumps resembling somewhat a segmenting form Small particles of sediment or detritus from the staining solution often have a blue color and may contain granules of dirt resembling pigment These can be differentiated from the parasite by the absence of the small red-staining chromatin body Certain cases of malaria in which the parasites are so few in number as to be missed in the ordinary examination may sometimes be recognized by the method suggested by Ross For this, thick blood smears are made, so that a good many layers of blood corpuscles are superimposed one on the other After drying in the air, they are carefully immersed in clear water until all the hemoglobin is dissolved out They are then fixed and stained in the ordinary manner The crescents of the estivo-autumnal fever stand out prominently, but the other smaller forms of the parasites would be lost among the mass of leucocytes present The laking of the blood may be hastened by employing a dilute solution of acetic acid, e g, 0.5 per cent, and afterward neutralizing with a weak solution of ammonia water The best time to study the blood is just before a chill, as it then contains the adult pigmented forms which are the easiest to recognize

The leucocyte count in malarial fever shows a normal or decreased number of these cells This is a most important point in diagnosis and serves at once to differentiate this disease from many conditions associated with a remittent or intermittent temperature curve In 82 recent cases of estivo-autumnal fever at the Johns Hopkins Hospital¹ the mean leucocyte count was 3,500 per cm³ with only seven cases above 10,000, and in tertian infection the mean count was 4,500 in 70 cases with five above 10,000 It is almost impossible to lay too much emphasis on the value of a leucocyte count in all cases of fever, as it immediately places the case in one of two groups, thus eliminating a large number of possible conditions which, like malaria, may be accompanied by chills and an irregular fever A leucocytosis may occur in the paroxysms of pernicious malaria, in certain rare cases of malarial hemoglobinemia, and with the occurrence of complications

The differential count of the leucocytes, while possibly not so instructive, is often most suggestive In malaria there is a pronounced increase in the relative number of the large mononuclear cells with a diminution in the number of small lymphocytes and the polymorphonuclears Of late much importance has been attached to these facts especially in certain cases of probable malaria in which prolonged search has failed to demonstrate the plasmodium Delaney² concludes that an increase in the proportion of the large mononuclear cells from the normal 1 or 2 per cent to or beyond 12 per cent is highly suggestive of malaria Kraus³ of Memphis, has reported the findings in 204 cases in which the average proportion of the large mononuclears was

¹ Emerson Clinical Diagnosis J. B. Lippincott Company 1906

² Brit. Med. Jour., March 28, 1903.

³ THE JOURNAL Oct. 22, 1904

19.5 per cent, while that of the small lymphocytes was 14.8 per cent, and he lays particular emphasis on the relative increase of the large over the small mononuclears. The mean average in a large number of cases at the Johns Hopkins Hospital, as given by Thayer,⁴ is 16.9 per cent of large mononuclears. These cells may also be increased in typhoid fever (after the second week), measles, syphilis, and possibly in influenza, but not to the same extent as in malaria. Of course, an adenopathy must be excluded. It is not safe to rule out typhoid fever when the malarial variation is found, especially when the disease is of some duration, but in a gradually developing fever the absence of a marked increase in the large mononuclear cells during the first week speaks against malaria and suggests typhoid fever. A differential count of the leucocytes is not a difficult procedure and, in fact, can be done at the same time that one is searching for the plasmodium in a stained blood smear by counting and classifying the white cells as one goes over the field.

The anemia of malaria is of some importance in diagnosis, as it is an early symptom, and in severe estivo-autumnal infections there may be a destruction of 1,000,000 cells per cm. in one paroxysm. The regeneration of the cells is rather rapid, and in the tertian and quartan types the count may be restored before the next rigor, and the anemia only occur after a long series of chills. The hemoglobin suffers more than the red cells and returns to normal more slowly.

Therapeutic Test—"An intermittent fever which resists quinin is not of malarial origin," Osler. Numerous clinical experiments have demonstrated that the tertian and quartan forms of the parasite are peculiarly susceptible to the action of quinin, and a common experience in my hospital service has been to put a stop to all subsequent chills by the administration of ten grains of quinin four or five hours before an expected chill. Of course, it does not prevent this chill, but the drug is in the blood in sufficient quantity to destroy most of the young hyaline forms produced by segmentation at the time of the paroxysm. The estivo-autumnal type of infection is more resistant to the action of quinin and it may require three or four days to sweep most of the organisms from the blood. That this form of malaria is quite amenable to treatment, however, is well demonstrated by Carter's⁵ experience with over 200 cases of estivo-autumnal fever in the canal zone at Panama. His patients are given thirty grains of quinin a day and show an average duration of fever of 52 hours and an average stay in the hospital of five days. Next to the examination of the blood, the therapeutic test offers the most convincing proof that the disease at hand is malaria, and if the symptoms do not promptly abate with the proper exhibition of this drug one may be certain that he is dealing with a condition other than malarial fever. It is true that doubt may arise in mild cases of some of the maladies mentioned below from which the patient recovers from the rest in bed and the general measures employed in spite of the quinin!

SYMPTOMATOLOGY

The clinical forms as given by Osler, include first, the regularly intermittent fevers, the tertian and quartan types with the quotidian fever, due to a double infection with the tertian organism, second, the irregular,

remittent, or continued fever, the estivo-autumnal type, which may be combined in a double infection with the tertian parasite, and, indeed, cases are on record in which all three forms of parasites have been demonstrated, third, pernicious malarial fever, which is always associated with the estivo-autumnal parasite, and fortunately quite rare in temperate climates. It is in this form that one meets with the real "congestive chill" or "yellow chill" and occasionally with hemoglobinuria, fourth, malarial cachexia, characterized by anemia and an enlarged spleen, the result in cases frequently exposed to infection over long periods of time and not thoroughly and energetically treated.

DIFFERENTIAL DIAGNOSIS

There is rarely any doubt in one's mind when dealing with the regularly intermittent fevers. The acute onset without prodromal symptoms, the sharp rigors occurring with remarkable regularity, and the prompt disappearance of all symptoms on small doses of quinin give rise to a clinical picture that is at once appreciated. The estivo-autumnal infection, however, may run its course without definite paroxysms or may assume atypical forms and is most often diagnosed as typhoid fever. Experience in many cases at the Johns Hopkins Hospital have shown that it is impossible to distinguish these cases without a blood examination. It should be emphasized that this form of paludism is not at all uncommon in this climate, and it is of the utmost importance to recognize it. Pernicious malaria, in which thrombi of parasites may occur in the cerebral or mesenteric vessels, causing the so-called comatose and algid forms of the disease, may pass as meningitis, uremic coma, dysentery, yellow fever, or even Raynaud's disease (case with superficial gangrene). Malarial cachexia must be differentiated from pernicious anemia, leukemia, splenic anemia, Hodgkin's disease with splenic involvement, etc. It is only by a thorough study of the blood that the diagnosis can be reached in these atypical cases, and the discovery of a single crescent will give indication for most vigorous treatment.

The error is more often made on the other side, however, and the number of human ills placed in the category of "malarial fever" is legion. As a result, the municipal health is jeopardized by the infectious diseases that fail to be recognized, precious time is wasted in establishing the proper course of treatment for the case, the unfortunate patient is dosed with cinchonin *ad nauseam*, the prognosis is in doubt, and naturally both the victim and the physician are dissatisfied. It is with some of these conditions that this paper has to deal. They are chiefly as follows:

Typhoid Fever—That this disease is frequently diagnosed as malaria must be apparent to anyone who looks into the statistics as to the cause of death published by various health boards throughout the country. One reads with astonishment in the U. S. Census Report for 1890 that in Brooklyn the deaths from malaria for the preceding six years aggregated 1,413, while only 1,002 deaths were attributed to typhoid fever during this same period.⁶ At the same time Brooklyn was credited with having a remarkably low death rate from typhoid fever. Now, any reasonable physician must admit that a death from malarial fever is a rarity north of Mason and Dixon's line, and much the same may be said of this locality. A study of the conditions in Richmond, however, is very interesting. The reports of the health de-

⁴ Johns Hopkins Hosp. Rep. vol. v.

⁵ Dr. H. R. Carter. U. S. Marine-Hosp. Service, personal communication.

⁶ Osler. Med. News, Nov. 23, 1895.

partment in this city for the twenty years ending 1905 give the following total number of deaths as turned in for these two diseases

Typhoid fever	768 fatal cases
Malarial fever	282 fatal cases

Thus there were more than one-third as many deaths reported from malarial fever as from typhoid fever. In addition, during these same twenty years there were 79 deaths reported as due to "intermittent fever" and 29 fatal cases of "remittent fever." Add these to the number of fatal cases of malarial fever and we have a total of 390 deaths ascribed to malaria, intermittent and remittent fever, or more than half the number of fatal typhoid cases. As an evidence that these statistics are not the work of a passing generation of physicians, but are dependent equally on the diagnostician of the present day, it might be well to cite the record of Richmond's health board for the one year 1905, which shows

Typhoid fever	28 fatal cases
Malarial fever	24 fatal cases

Such figures as these would seem to make it imperative, as some writers have previously suggested, that our health boards examine very closely into all deaths reported as due to malarial fever.

Failure to recognize a case as typhoid fever may be due to the occurrence of chills, which, it must be remembered, are not uncommon in this disease. In the first place, typhoid fever may set in with shaking chills. This happened in 13 out of the 79 cases treated at the Johns Hopkins Hospital during the year 1894.⁷ In two cases there were several severe rigors, in three cases there were two, while in eight the rigor was single. Chills may also occur⁸ at the onset of a relapse, as a result of treatment especially following the use of antipyretics at the onset of complications, as pneumonia or femoral thrombosis, and chills may be present throughout the course of the disease associated with sweats, the so-called sudoral form. How often may chills be due to a concurrent malaria? This brings up the question of typho malarial fever as a clinical entity, which will not be discussed in this paper. Suffice it to say that the health board reports for Richmond show the return of 215 fatal cases so diagnosticated from the years 1887 to 1900, inclusive. After 1900 all cases reported under this head have been included under typhoid fever in accordance with the International Classification of the Causes of Death, adopted in that year. It is not to be denied that these two diseases may co exist in the same patient, as was shown by Gilman Thompson⁷ at the meeting of the Association of American Physicians in 1894, as in his cases the parasites were actually demonstrated in the blood. These cases must be excessively rare however, as Osler⁸ reports 829 cases of typhoid fever in which examination of the blood revealed the plasmodium only once.

Typhoid fever at its height is a continuous fever, and the temperature curve rarely shows daily variations of more than a degree. Malarial fever, on the other hand is marked from the outset by remissions of a grade not seen in the early weeks of typhoid. Say what one will however, estivo-autumnal malaria may simulate enteric fever very closely and it is just in these cases that the diagnostic importance of a blood examination comes in. The practitioner should be able to exclude malaria and in most states there are city or state laboratories where

a specimen of blood may be sent for a Widal test. A reasonable reliance may be placed in the therapeutic test, but if distinct results are not produced at the end of a week it is worse than useless to continue dosing the patient with quinin. Dr Osler⁸ expresses it admirably when he says "Learn to suspect typhoid fever, and not malaria, in every case of fever of six or seven days' duration, particularly if it resists the action of quinin. For too long you have employed the Anglo-Saxon method of procedure, and in a given case have assumed innocence of anything so serious as typhoid until in the onset of some serious symptom the guilt was only too evident. It is high time now that you adopt the Gallic usage, and regard every case of continued fever as guilty, that is as a typhoid, until the contrary be clearly demonstrated."

Pulmonary Tuberculosis—Fever is often the initial symptom in pulmonary tuberculosis especially in the more acute cases. It is either remittent or intermittent continued fever being unusual except in some cases of tuberculous pneumonia. The similarity between the temperature curves of phthisis and malaria is sometimes very striking. Not long ago there was a young woman under my charge with acute tuberculosis of the lung whose daily variation in temperature was over seven degrees—96 to 103—for nearly two weeks. Special emphasis should be laid on the fact that tuberculosis may set in with shaking chills, fever and sweats, and combined with this there may be few, if any, physical signs. In such cases consumption may not even be suspected until at the end of several weeks, during which time the malady and perhaps the patient have been quite refractory to large doses of quinin, a beginning cough or even an hemoptosis may put the practitioner on his guard. On the other hand, malaria may be accompanied by a pretty marked bronchitis, and a distressing cough may take the place of the chill, as in a recent patient of mine, during the paroxysms. So in many cases the correct diagnosis can be reached only by a careful examination of the blood and sputum.

Pyelitis—Infections of the pelvis of the kidney as well as certain other inflammations of the genito urinary tract, are probably more often mistaken for malarial fever than any other condition. The insidious onset without pain or local symptoms, the characteristic intermittent or remittent temperature line and chill occurring with peculiar regularity, all suggest malaria most strongly. The rigors in such cases are probably associated with a temporary blocking of the ureter-drain either by a calculus or by inflammatory products, as the urine during the fever may be clear and free from pus, while at the termination of the paroxysm turbid urine loaded with pus is voided. It seems very strange that these forms of pyelitis associated with fever rarely cause any symptoms even when the disease is extensive. Palpation may reveal an enlarged and tender kidney, but not necessarily so. In contrast to malaria there is usually a leucocytosis of moderate degree. 12 000 to 20 000 the blood does not show the plasmodium while one or two urinary examinations usually puts one on the right track.

Chills and high fever following urethral instrumentation is an exceedingly interesting condition not often however confused with malaria as it occurs soon after the local manipulation. Chills and intermittent fever may ensue on the passage of a renal calculus.

Septicemia and Pyemia—Originating not infrequently from an insignificant focus, they may not be

⁷ Trans. Assoc. Am. Phys. vol. ix.

⁸ Osler's N. Y. Med. Journal, Nov. 4, 1899.

discovered, these serious conditions pursue a course closely resembling malarial fever. While septicemia has often but one initial chill and then runs a more or less continuous fever simulating typhoid, which in itself is a septicemia, pyemia, on the other hand, has as its cardinal symptoms irregular fever, chills and sweats. The diagnosis of these infections from malarial fever is almost always suggested immediately by such a simple measure as a leucocyte count which shows a distinct increase in the number of colorless corpuscles. Of course, every means should be employed to locate, if possible, the initial lesion. Cases following a wound, surgical operation or child-birth are readily recognized, but the process may originate in the tonsil or accessory nasal sinuses, may follow gonorrhea or a prostatic abscess, or occur in several of the following conditions which, because of their importance, are taken up separately.

Acute Endocarditis—Under the title, "The Pseudomalarial Types of Infective Endocarditis" Coleman,⁹ in an excellent article, shows a good many temperature charts illustrating the following pseudomalarial curves: double quotidian, quotidian, tertian, quartan, and mixed types. He cites several illustrative cases, states that the paroxysms may be identical with those of malarial fever, presenting cold, hot and sweating stages, with fever-free intervals, in which the cold stage may be accompanied by a prolonged, hard chill. As is well known, an acute process may attack the heart valves and give rise to no physical signs or symptoms until broken compensation ensues. In both malaria and acute endocarditis the long-continued hemolysis results in the deposit of pigment in spleen, liver and bone-marrow so that postmortem it is unsafe to attempt to distinguish malaria from septic processes merely on the gross or microscopic appearance of pigment in the viscera. This author concludes that the only reliable method is the demonstration of the malarial parasites in cases of this disease and their absence in septic processes. In nearly all other respects the pathologic anatomy of pernicious malaria may be closely reproduced by septicemia.

Liver Abscess—Suppuration within the liver is most frequently secondary to amebic dysentery, but may follow traumatism or occur as a part of a general pyemia, or as the result of foci of suppuration in the territory of the portal vessels. As regards symptoms, the hepatic abscess may be entirely latent, but as a general rule there is pain associated with fever and an enlarged liver. The temperature is usually intermittent and rigors are not uncommon, which, associated with the sweating, form a clinical picture not unlike malaria. In the case of the amebic abscess the patient may give no history of dysentery,¹⁰ but a careful examination of the feces generally reveals the protozoan. The blood does not show the malarial parasite, but may exhibit an eosinophilia, Billet¹¹ having reported 32 cases in which this was a constant feature. Most of his cases showed from 5 to 12 per cent of eosinophiles, with one case running as high as 47 per cent. My experience does not entirely confirm this, as my notes on 14 differential counts in cases of amebic dysentery occurring recently in the wards at Johns Hopkins show that the eosinophiles were less than 4 per cent. in seven, and the case with the highest number had only 9.8 per cent. Amberg¹² found a slight eosinophilia in some cases of amebic dysentery in children, in others none. As a rule, there is an increase in

the number of leucocytes in abscess of the liver, but a certain proportion of the cases fail to show it,¹⁰ so that absence of leucocytosis does not aid in the differential diagnosis.

Gall Stones—One form of cholelithiasis so frequently simulates malaria as to be worthy of special notice. This is obstruction of the common duct with the stone lodged in the diverticulum of Vater and exhibiting a ball-valve action. This is apt to give rise to ague-like paroxysms, chills, fever and sweating, the so-called hepatic intermittent fever of Charcot. I have seen several such cases giving a history of intense rigors over periods of weeks and months with more or less irregularity, fever often mounting to 103 or 104, that had been treated continuously with quinin, in which Dr. Halsted operated and confirmed the diagnosis of stone in the common duct. The most careful search failed to reveal any malarial organisms in these cases. The patients all showed more or less jaundice which had been considered in the light of the icteroid tint so frequent in severe malaria. The pain in these conditions, while sometimes severe and colicky, does not always occur. A careful consideration of all the symptoms, the deepening of the jaundice after each paroxysm, the presence of bile in the urine and the absence of the plasmodium in the blood should lead one to the correct diagnosis.

Among other diseases that may run irregular and intermittent fevers should be mentioned the severe anemias, leukemia, and especially Hodgkin's disease in which periods of pyrexia may alternate with periods of normal temperature, or there may be a daily rise of three or four degrees, sometimes with a chill and sweat. The fever in the early secondary stage of syphilis may assume marked intermittent character and this may also be said of the fever in certain instances of malignant disease. In children, milder forms of osteomyelitis, when not attributed to "growing pains," are often ascribed to malaria,¹³ and when a child is brought to us with limp paralyzed extremities how common it is to have the mother tell that the whole trouble began with an attack of malaria, when the acute symptoms were really the onset of an anterior poliomyelitis. These conditions, and possibly many others, are treated as malaria and will continue to be so diagnosed until the practicing physician realizes that malaria is a real clinical entity, with a well-known and easily found causative agent and with an antidote that is a specific in every sense of the term if properly exhibited.

TREATMENT

The subject of prophylaxis will not be dealt with in this paper except in so far as it applies to the individual patient. In all well-directed hospitals every patient whose blood harbors the malarial parasite is covered at night with a mosquito net, at least during the months that the anopheles are present. Were this not done ward infections would not be infrequent owing to the habits of this mosquito, which does not migrate, but tends to spend its whole existence within the radius of a few hundred yards. This insect bites only at night, and a mosquito bar is not an inconvenience and we would all do well to insist that one be provided in each individual case we treat. If it were possible to isolate every case of malaria, including the instances in children that are only too often unrecognized, the disease could be quite eradicated.

In the treatment of the individual case emphasis must

be laid on the following points 1 The quinin must be absorbed and enter the blood 2 The drug must be administered until every parasite is destroyed 3 The patient should remain in bed until the temperature reaches normal and remains normal

In order that the quinin be absorbed there are two essential features to which attention may be directed 1 The patient's alimentary tract should be in a condition to favor absorption To this end the bowels must be unloaded by means of a good dose of calomel or blue mass, followed by a saline The diet should consist of soft, easily digested foodstuffs, and as long as there is fever liquid diet alone is preferable 2 The quinin must be given in a soluble form In this connection I should like to cite briefly a rather remarkable case that came under my notice a couple of years ago A man was brought into the hospital in a state of collapse whose blood presented an extreme picture of pernicious malaria, nearly every other red cell containing one or more parasites He died in a few hours in spite of heroic treatment, and at the autopsy was found an ischio-rectal abscess which contained in its pocket-like recess a very large number of quinin pills which had passed through the intestine without being at all dissolved Such an experience as this is certainly striking enough to condemn forever the administration of quinin in pill form Undoubtedly the surest way to give quinin is in solution with a mineral acid, e g, quinin sulphate 5 grains, dilute hydrochloric acid 5 minims, water to 1 dram It is not very palatable, although the acid seems to offset somewhat the bitter quality of the quinin, and I have always found that patients take it without objection The drug may be administered in powdered form in soft gelatin capsules, but it is not an uncommon experience to have them pass entire from the rectum The solubility of the quinin when given in this form is aided by following the dose in a few minutes by 10 minims of dilute mineral acid The best indication we have that the quinin is absorbed is the subjective sensation of ringing in the ears, and if this is lacking we may feel quite sure that the quinin is not in the blood except possibly in certain unusual cases of idiosyncrasy in this regard

The necessity of giving quinin for a definite period after the fever and symptoms have disappeared is not always sufficiently appreciated This fall I have had several patients brought to me who gave a history of chills and fever five or six weeks previously, who had been given quinin for a few days which caused the symptoms to abate, but they have never felt quite well since, complaining chiefly of periodic headache, malaise and occasional chilly sensations, and on examination the blood still showed the plasmodium A good general procedure in the handling of ordinary cases is the following 5 grains of quinin every four hours, or 20 grains a day, for the first five days, then $2\frac{1}{2}$ grains every four hours, or 3 grains three times a day, for two and a half or three weeks In severe cases larger amounts may be given, 30 to 40 grains daily It is generally advisable to give one large dose, 10 or 15 grains, five hours before an expected paroxysm and if this is done there is usually sufficient quinin in the blood to destroy most of the young hyaline forms that are produced by segmentation during the chill But if a case is seen directly after the rigor and another is not expected for two days I much prefer to start the quinin at once as it is undoubtedly true that a certain number of parasites are destroyed by the quinin while still contained within the red corpus-

cles¹⁴ and the succeeding paroxysm is much modified Let it here be again emphasized that quinin is a specific in malaria, that if it enters the blood in sufficient quantity the fever should disappear in a few days certainly within a week, and I doubt very much if it is possible under these conditions for malarial fever to run as long as thirty days, a remark that is sometimes heard Dr Carter's communication, already mentioned, touches directly on this point, as in over 200 cases of estivo-autumnal fever treated in the canal zone at Panama the average duration of fever was only 52 hours in this severe type of infection

In pernicious malaria every means should be employed to get the quinin into the circulation as quickly as possible The drug must be given hypodermically—or rather, intramuscularly—or even intravenously, and may also be given by the rectum Tyson objects to the hypodermic method, stating that he has had to abandon it on account of the frequency with which it is followed by abscess formation Undoubtedly quinin is very irritating to the tissues, but if the precaution is taken of injecting it deeply into the muscles and not simply under the skin, abscess formation is less often encountered At least, this has been the experience in Panama,⁵ where this method is frequently used The bimuriate of quinin, or the bisulphate of quinin and urica, are the two preparations most frequently used These methods of administering the drug are dealt with in most textbooks on the subject

The necessity for absolute rest in bed while actively combating the infection must be apparent to anyone who has tried the simple experiment of treating an ordinary case of tertian malaria by this means alone without the use of quinin at all While by no means the best way to kill off the parasites yet it is surprising to see what Nature can do when aided by rest diet, care of the bowels, and general hygienic measures It is very certain, however, that the rest plus the quinin is more efficacious than either alone

Appropriate means should be employed during the paroxysms to make the patient as comfortable as possible—blankets, hot water bottles and possibly a hot whisky-and-water The judicious use of morphia is often indicated, especially if there is much gastric disturbance A tepid sponge or an alcohol rub is appreciated during the sweating stage

The post-malarial anemia is best treated with some form of arsenic I usually prefer Fowler's solution running up to 10 or 12 minims three times a day, provided the patient takes it well Some prescribe a combination of iron and arsenic in pill form If there is any indication to continue quinin, such a tonic as the syrup of iron, quinin and strychnin phosphate may be given

The whole question of the treatment of such a common disease as malaria is so simple if attention be directed to certain important details that this fact is probably the very reason we turn out so many students from our medical schools each year with only a hazy idea of the subject

110 North Fifth Street.

Sudden Death in Apparently Healthy Infant.—C J Bartlett of Yale states, in *Yale Medical Journal* that in cases in which an apparently well nourished baby dies suddenly without evident cause he always expects to learn that it has been fed on condensed milk or some baby food in place of cow's milk and that he is not usually disappointed

NUTRITIONAL DISTURBANCES IN INFANCY
DUE TO OVERFEEDING *

JOSEPH BRENNEMANN, M.D.

Instructor in Pediatrics, Northwestern University Medical School.
CHICAGO

That overfeeding in infancy is apt to be followed by indigestion is a universally recognized fact. The term, however, usually suggests the giving to an infant of a food that is too rich in one or more food elements, or that is unsuitable to age and conditions, or that is given in too great variety and at too short and irregular intervals. We have not been sufficiently impressed with the fact that even an appropriate artificial food and one properly adapted to the individual case, can give rise to the profoundest nutritional disturbances when given in quantities that exceed the actual economic needs of the infant. In this discussion the term overfeeding will be used in this restricted sense, the giving to an infant of too great a total quantity of good, clean, fresh, unexceptionable, properly modified cow's milk, usually, but not necessarily, at too short intervals.

Continental writers have emphasized the danger of overfeeding in this sense for many years. Biedert was among the first to teach a doctrine of minimum feeding (*Minimálnahrung*), which called for the smallest amount of food necessary to insure perfect development with normal increase in weight. This most desirable minimum daily amount of food he placed at from 150 to 200 grams of fluid per kilogram of body weight, this amount to contain about 80 calories.

Heubner determined along metabolic lines the number of calories, per day, per kilogram of body weight, necessary to insure proper development in normal breast-fed babies. This so-called energy quotient he found to be about 100 from the third week to the end of the sixth month, a gradually diminishing amount after that time to about 80 or 85 at the end of the first year. He established 70 as the approximate energy quotient necessary to maintain a weight equilibrium.

Clinical observations, each extending over many months, have been made on breast-fed infants by Feer, Beutner, Budin, Schlossman, Nordheim, Czerny and Keller, Reyer and others, that have all confirmed rather closely the figures set down by Heubner, so that these can be used as a standard.

Budin of Paris uses a simpler measure. He feeds all of his babies "especially after the fifth or sixth month, or better, weighing 6 or 7 kg, one-tenth of their body weight daily of pure, sterilized, undiluted milk," and claims to have no symptoms of the overfeeding against which he warns so emphatically.

In this country, through the teachings of Rotch, Holt and their followers, we have come to think of nutritional needs and overfeeding rather in terms of percentage than of amount. Certain standards are set up as guides to the strength of food a child should receive, and these naturally find expression in more or less elastic tables of percentages of different food elements adapted to average healthy infants at various ages. Weight is given comparatively little significance, and for conditions other than normal we have most indefinite data.

To Czerny and Keller we are indebted for a symptomatology of overfeeding that in its totality, is new and original and is so clean cut and palpable that it alone can serve as a real guide to determine when proper amounts are beginning to be exceeded. Their exhaustive

and truly scientific work¹ that has appeared only in part has placed the whole subject of infant feeding on as firm a foundation in reason and scientific investigation as that on which any other department of medicine stands. Finkelstein has put it none too strongly when he says "When in the future we shall speak of the attainments of scientific pediatrics, Czerny and Keller's work will be placed first, and everyone who wishes to occupy himself in a scientific manner with the problems of infant feeding must find his foundations there." I wish to acknowledge that this paper and our own recent work in infant feeding has been, in a large measure, inspired by this work, and especially by the chapter on *Milchnährschaden*, a term perhaps most briefly and fully translated by the title of the present paper, a chapter in which they picture a definite and convincing symptom-complex resulting from overfeeding.

For some time we have recognized and studied this clinical picture, we have also, during that time, calculated energy quotients in all of our feedings and have been much impressed by the results. It seemed to me additionally instructive to study our old cases in this light. I have, therefore, recently gone over the histories of our old cases at the Northwestern University Medical School, as well as over my own private cases, to see what our past habits have been with reference to overfeeding, both from a calorimetric and a clinical or symptomatic standpoint, and from this, if possible, to make a deduction as to the prevalence of overfeeding under present conditions in this country.

Our conditions have been rather favorable for such a study. In practically all of these cases we have a complete history of the exact amount of certified milk or cream, of definite strength, that was used, together with the exact weighed amounts of other ingredients used in the mixture. Our weight record, on our own scales, is quite complete, and the rest of the history as to bowel movements, disposition, etc., sufficiently so for this purpose. In nearly all cases the foods were prepared at the diet kitchen—always individually for each case. We have, then, all the necessary data for calculating approximate energy quotients. We have considered the caloric value of 1 ounce of 4 per cent milk at 21, 1 ounce of 16 per cent cream at 54, 1 ounce of skimmed milk at 10, 1 ounce of sugar at 120, 1 ounce of cereal water at about 3. It is a simple matter, then, to multiply the number of ounces of each ingredient in the twenty-four-hour food by its caloric value, to add the products, divide by the number of pounds the baby weighs, and multiply the result by 2 1/5 to reduce from pounds to kilos. The end product is the energy quotient. By caloric value is meant the number of large calories, the latter being the universally recognized unit of measure of food value as expressed in terms of heat production and representing the amount of heat required to raise 1 kilogram of water from 0 C to 1 C.

The dispensary babies were fed by a number of different instructors connected with the department of pediatrics. Until recently we all used the percentage method. We have however, gradually come to look on fats with that feeling of caution that pervades our own literature (Holt, Southworth, Jacobi, etc.), and I believe that all of us fed considerably under the usual amounts rather than above them, especially of fat. In the last year most of us have stopped using cream altogether and have used only milk dilutions with the addition of carbohydrates. I believe, then, that I can assume that our

¹ Des Kindes Ernährung, Ernährungsstörungen und Ernährungstherapie.

conditions were representative, or at least not an exaggeration, of what is being done in this country by those who use these methods only

I was convinced before looking over our records that overfeeding was a factor in our results, but after studying them, I am positive that, in our past, overfeeding has been a factor in the production and maintaining of nutritional disturbances in infants that towers above all others

It seemed impossible to tabulate these cases and have the results of any more value than are general statements, so I have not attempted it. As far as calorimetric overfeeding is concerned, according to Heubner's standard, it can safely be stated that all of our cases were overfed ultimately, except those that were, at the time, suffering from some acute disorder. By overfeeding is not meant simply the exceeding of Heubner's energy quotient of 100, but rather using energy quotients of 120, to 150, to 200—in one case, fed by a physician not connected with the dispensary, who had had peculiarly valuable experience in infant feeding by the percentage method, an energy quotient of 330 was given for two weeks

SYMPTOMS OF OVERFEEDING

As to symptoms due to overfeeding, it can be said with equal certainty that they were present in the great majority of our babies, at some time, during the period that they were under our care. So typical and uniform are these symptoms that we associate with overfeeding that they form a clean-cut, easily recognized clinical entity. Individual cases differ from the well-marked type only in the number and the degree, rather than in the character of the symptoms, that make up this symptom-complex. Many of our cases gave only a few slight manifestations of trouble that had little or no bearing on the general condition of the child, in others there was every evidence of the profoundest nutritional disturbance

An infant that is overfed becomes restless, often most strikingly shown by broken and restless sleep at night. At the same time it becomes constipated in a very characteristic manner, the bowel movements that were yellow in color and were soft and moist, become pale gray, hard and dry, will not mix with water, and are of the color and consistency of putty—so that they will roll from the diaper without leaving it soiled. The odor is strong and suggests decomposition. The urine has commonly a strong ammoniacal odor and easily produces irritation of the skin.

At the same time it is noticed that the child gives evidence of a fundamental disturbance of nutrition. It becomes pale, its tissues lose their tone, the abdomen becomes soft and moderately distended with gas. The child becomes less active, it plays less. A striking symptom, often the only one that gives any concern to one not familiar with this picture, is a failure to gain in weight on the same food, or a greater quantity of food than up to this time has produced normal or even abnormal gain in weight. Still more striking is the fact that a continuation of the same amount of food, or of an increased amount, will regularly produce not only a stationary weight, but after a time, a steady loss in weight. A further increase in food may again produce a temporary gain often a large one but it only makes surer and quicker the ultimate loss in weight.

OTHER RESULTS OF OVERFEEDING

If this course is persisted in one of two results will follow. The child finally presents the picture of atrophy

or marasmus. This we see not rarely in the pale constipated, marantic baby that gives the history of having had a stationary weight, or steady loss in weight for months, in spite of the fact that it has taken enormous quantities of cow's milk and has had no diarrhea or evident digestive disturbance.

The other result is the acute gastrointestinal catastrophe that may occur at any time in this course and that is characterized by vomiting, diarrhea, prostration, loss in weight, often by fever, and usually, by the inability to take more than the smallest amounts of cow's milk, sometimes for many weeks. This condition we have seen more commonly in weaker children with poorer digestion, especially in those who were rapidly or excessively overfed, while in more robust children with better digestion, in whom the overfeeding was a more gradual process, though excessive there has been more of a tendency to the typical chronic course outlined above. In weaker children one often sees one catastrophe follow another, especially in hospital cases the only progress being made during the period of low feeding generally recognized as necessary after such an upheaval, while in the stronger children the severest symptoms of overfeeding may be present for months before such a catastrophe occurs, if it occurs at all.

In many of these more chronic cases there is evidence of rickets, with the train of nervous symptoms that accompanies that disease. Two other symptoms very frequently appear at some time during the period of overfeeding. One of these eczema, has been very frequent in those of our cases that have shown other well-marked symptoms of overfeeding especially the characteristic constipation. It varies from the small, rough reddish spots in the cheeks that are so well known to the most extensive and intractable involvement of the cheeks, forehead, scalp, chest and back, and other parts of the body.

The other symptom alluded to is anorexia. Loss of the normal keen appetite of infancy, so that the child needs to be coaxed to finish its bottle, is very common in these cases that are well marked, but a refusal to take more than an ounce or even less, at a time, is characteristic only of the graver cases, and then often forebodes a catastrophe. We have come to look on this symptom as due to overfeeding in practically all cases in infancy in which there is not some other evident acute, or chronic disorder. There is at present at Wesley Hospital a child of 17 months weighing 16 pounds in whom an increase of food from 26 ounces of milk, 10 ounces of barley water, 1 oz of cane sugar to 30 oz of milk and 6 oz of barley water produced in one day a florid eczema of chest and back spreading later to the cheeks and scalp, and within five days, loss of appetite, restlessness at night, fever and constipation, with hard, dry, gray bowel movements.

While most of our babies gave some evidence of overfeeding and many of them had well-marked manifestations, such as constipation, pallor, restlessness, etc., stationary weight, etc. there were very few in whom the final outcome was wholly bad. The ultimate picture of marasmus, of course came to us in its finished state and was never produced by us. Some of our cases showed undoubted rickets although under satisfactory control throughout. In general we considered our results excellent. In some cases this was due not so much to our methods as to the fact that these cases can often stand a surprising amount of overfeeding. While some of our cases did well for a while and in

of 150, many gave evidence of serious trouble on those of from 110 to 120 or even less. Since calculating energy quotients in all of our cases we have seen few, if any, cases that required over 100, and we have usually regretted it if we have exceeded that "unsurpassable amount" (Heubner). In general, we have found the energy quotients of from 100, at the beginning, to 80, or less, at the end of the first year, as a wholly satisfactory working basis as to the approximate amount of food a child should get.

FAT THE DISTURBING ELEMENT

There seems little doubt that the disturbing element in this condition is the fat of cow's milk, and that its non-digestion, non-assimilation and the resulting disturbed intermediary metabolism are the cause of this train of symptoms. Outside of the negative evidence that proteids and carbohydrate and salts can not produce this picture, there is very positive evidence that fat does. The characteristic dry, hard, pale bowel movement has been found to consist largely of the insoluble salts of the fatty acids (*Seifenstuhl*). If the amount of fat is increased all symptoms are increased. If the fat is sufficiently diminished, and the other food elements are left undisturbed, or increased, there will be rapid improvement. No other result in infant feeding is more striking than the mathematical certainty with which the dry, gray bowel movements of these infants, no matter what their ages, are replaced by characteristic smooth, nearly odorless, curdless, brown, salve-like bowel movements, when they are fed straight, undiluted skimmed milk—a food that is nearly fat free, but contains the maximum amount of proteids and carbohydrates. Nor is the general improvement less certain than that of this one symptom.

The immediate cause of this condition is probably an acidosis (Czerny and Keller), as shown by increased excretion of ammonia in the urine. This is due to the fact that alkalies are withdrawn from the body by the fatty acids produced in the intestines and to satisfy the normal acid products of metabolism ammonia is called on.

The following three cases may be cited as typical cases of overfeeding, in which the percentage method was used.

CASE 1—Baby F, well developed, strong, healthy baby. Birth weight 9 pounds 12 ounces. Maternal nursing alone for three weeks, with severe indigestion and considerable loss in weight. After the first month fed artificially on cream and whey mixtures, later on cream and milk. At four months weighed 13 pounds 8 ounces. At five months weighed 13 pounds, a loss of 8 ounces in one month. During this month the child had received a food mixture containing fats 30, proteid 20, sugar 70. Seven feedings of 5 ounces each were given at three hour intervals. The energy quotient here was about 110. It did not take the food well and would often leave one or two ounces of a 5 ounce bottle. Child was rather pale and thin, but muscular and active. Cranio tables well marked. Bowel movements were pale yellow and somewhat dry and offensive. During the fifth month a sudden severe diarrhea occurred, with from twelve to fifteen green bowel movements a day. It was put on barley water for a short time and milk, later cream, was slowly added. Baby now took food eagerly and after the initial loss due to diarrhea and hunger diet, gained one pound in two weeks. Soon began again to refuse to take all of the 5 ounces of food, so the food was made more concentrated. Fat 4, proteid 2, sugar 75. The number of feedings was kept the same as also was the frequency and the amount. The energy quotient now was about 137. Child became rather constipated, the bowel movements were pale greenish yellow and offensive but it gained 20 ounces in eighteen days on this stronger food.

Two weeks later there was no gain in weight, the bowel movements were dry, pale and offensive, the baby was pale, and refused food more and more. Finally it would take only an ounce or two at a time, and was losing in weight. In three months it had gained only 1½ pounds. The mother then, on her own initiative, fed the child potato, bread and gravy, porridge, cracker, soup, etc., and stopped coaxing her to drink milk, the child soon taking less than a pint a day. There was immediate improvement. The child was happier and slept better, bowel movements became normal, and the child gained a little over a pound a month for four months. At eleven months the child weighed 19 pounds. Still rather thin and pale, but marked improvement over former condition. Only very slight evidence of rickets.

In this case the most serious results of overfeeding were avoided by the mother unconsciously meeting the two therapeutic indications, decreasing the milk and increasing the carbohydrates.

CASE 2—Baby B, weight 11 pounds at birth, maternal nursing insufficient. Was rather underfed for two months, with stationary weight, for the next four months it gained steadily about 6 ounces a week on cream and milk mixtures. During the last two months of this time the child was badly constipated, one or two hard, dry, smooth, pale yellow bowel movements a day, offensive in odor. Eczema was first noticed about this time on cheeks, and later about the ears, then on the forehead and scalp, with one or two small spots on the body, it was variable in intensity. Child always rather pale, but very active and a good baby. During this time the food had a percentage never stronger than, fat 36, proteid 20, and sugar 65, but the energy quotient was from 160 to 165. The cream was diminished and the milk increased so that at nine or ten months the child was practically on about 40 ounces of whole milk, with the energy quotient under 100. Weighed 19 pounds at nine months, and the general condition was excellent. The eczema, which in this case was the chief symptom had slowly disappeared, and was practically gone at nine months.

CASE 3—Baby O, a typical case with all the classical symptoms, weighed 7 pounds at birth, was wet nursed five months when it weighed 16 pounds 4 ounces. Had been on milk and cream mixtures since then. At seven months the food mixture consisted of fat 30, proteid 15, and sugar 60, with an energy quotient of 86.

At eight months the child weighed 18 pounds and the food mixture was Fat 40, proteid 20, and sugar 70, the energy quotient being 128.

At nine months Fat 40, proteid 28, sugar 60, with energy quotient 130.

At ten months Fat 40, proteid 30, and sugar 60, energy quotient 130.

At eleven months the child weighed 18 pounds 14 ounces—a gain of 14 ounces in three months, the energy quotient was 128.

When one year old the child weighed 19 pounds 8 ounces. The food was milk 40 ounces, sugar 1 ounce, with an energy quotient of 108. During the last few months this child has had no acute illness. Has been out of doors almost constantly. Bowel movements have generally been rather dry, grayish, often nearly white and offensive, typical *Seifenstuhl*. Has had slight eczema for some months, especially recently, is rather pale does not drink well, and often leaves an ounce or two of food. When thirteen months old had for several days refused bottle more and more, and finally would not take it at all. The eczema was well marked, and vomiting and diarrhea now set in. Baby was put on barley water for eight days, then milk was added slowly to 40 ounces. At sixteen months of age the child weighed 20 pounds 10 ounces, a gain of 10 ounces in two months. In the last few months the child had taken a daily mixture of milk 40 ounces, sugar 1 ounce, in addition to some carbohydrate food granos, flaked wheat, etc. During the greater part of this time the stools had been hard, light colored and dry.

The child at sixteen and one half months was rather pale, the anterior fontanelle measured 1 inch across, the head was rather large and square, and the tissues soft. The ribs were

slightly beaded and the costal borders somewhat flared, the abdomen was soft and moderately distended.

This child lived under very favorable hygienic conditions, was out of doors nearly all of the time, was only moderately, but persistently, overfed, and yet developed mild rickets and gained only 24 ounces from the eighth to the eleventh month, or 2 pounds 10 ounces from the eighth to the sixteenth month.

TOO LARGE AMOUNTS VERSUS TOO LARGE PERCENTAGE

So far cases have been cited in all of which high percentages of fat have been used—only once a little above 4 per cent, in the rest 4 per cent or under. In a paper read before the American Pediatric Society in May, 1904,² Holt cites five cases resulting from too high percentages of fat (5 to 7+ per cent). These he details under the following headings:

HOLT'S SERIES—CASE 1—Overfeeding with high fat, rapid increase in weight and progress in development till 8 months old, then general convulsions followed later by tetany, laryngismus, fatty liver (!). Recovery after three months' illness.

CASE 2—Prolonged feeding with high fat, notwithstanding which constipation and the development of moderate rickets followed by acute disturbances of digestion with repeated convulsions.

CASE 3—Overfeeding with high fat, convulsions.

CASE 4—Habitual vomiting aggravated by high fat, serious gastric catarrh produced, finally cured by stomach washing.

CASE 5—Feeding with high fat, eczema, habitual constipation and finally habitual vomiting.

So striking is the similarity of this symptomatology to that of the cases I have just cited that there can be no reasonable doubt as to an identical cause, i. e., too much fat. This excess Holt repeatedly states in terms of percentages as if the essential point were too high a percentage of fat—not too great an amount. It may seem a trivial matter to point out this difference of viewpoint—and yet right here is the very kernel of the matter—the essential difference between feeding by a percentage method and a method that determines the amount of food that should be given. That these digestive disturbances are not due to too high percentages of fat *per se*, can be demonstrated with the ease and certainty of a laboratory experiment by any one who will feed a number of babies on low milk dilutions in excessive amounts, they will get the identical symptoms that Holt has described and that are undoubtedly due to too much fat.

A year ago I started about a dozen babies on simple milk and water, or milk and cereal water dilutions (1 to 3, to 1 to 0), with about 5 to 7 per cent sugar. Most of these babies were sick and required a preliminary one or two days' hunger diet. Such immediate results in the form of smooth, rich yellow, well-digested bowel movements I had never seen before. Gradually all those assistants in proteid digestion from alkalis to peptonization were dropped without any appreciable difference, except, in some cases a beneficial one. These babies were not constipated, they gained rapidly in weight from the start—there was not that long anxious wait in the sick cases that we were accustomed to in those we fed on whey and cream and cereal water mixtures. One after the other however these babies did become constipated, often very much so with pale hard, dry bowel movements. Some failed to gain after the first rapid gain. They became restless and did not sleep well at night. Many had eczema and some would not take all of their

food. Some of them gained steadily and well and seemed in good condition. Practically, all were ultimately constipated except those in whom sudden severe attacks of diarrhea broke out often without any apparent reason. We had been taught, and had ourselves taught that simple milk dilutions would "invariably cause constipation," so this result was not unexpected, and the other symptoms were considered secondary to it. In certain cases I added cream and found, to my astonishment that the condition was not only not relieved, but often made much worse.

I then began to estimate energy quotients in all cases and found that all of these cases had been overfed being given usually energy quotients from 120 to 170 during the period of eczema and maximum constipation or just before the catastrophe. Since we have calculated energy quotients in every case constipation has given us comparatively little trouble and the other symptoms of overfeeding no longer occur. We have heard much of "fat diarrhea" in the last few years. Fat constipation deserves at least an equal place in our nomenclature. We have come to look on fat as the constipator—and the one condition in which we have never seen constipation is the use of straight, skimmed milk, the maximum proteid and minimum fat food. A single case from this series will illustrate what has been said.

CASE 4—Baby E born March 14. Weight 10 pounds (?) and was wet nursed one month, but lost in weight, so was then fed on modified milk. Was first seen May 12, when it weighed 8 pounds 12 ounces. Had had a good deal of colic with three to four bowel movements daily, but was now constipated. Started the child on barley water for twenty-four hours, then 5 ounces of milk was added daily until it received the following: Milk 15 ounces, barley water, 25 ounces, sugar 2 ounces. The energy quotient was 154. The composition of the food was Fat 15, proteid 15 and sugar 60. Eight 5-ounce feedings were given daily at three-hour intervals.

May 5. Weighed 9 pounds 12 ounces, a gain of 1 pound in one week! The baby was well in every way, so the food was continued. This enormous gain in weight is characteristic of early rapid overfeeding and we now consider such a gain an imperative indication for reduction in the amount of milk unless the energy quotient is very low.

May 30. Weighed 10 pounds 3 ounces, had two or three bowel movements a day, yellow, not offensive but a little too hard and pale, so that baby grunts a great deal in passing them. Slight eczema. The same food was continued.

June 9. Weighed 10 pounds 13 ounces. Food the same, energy quotient, 123. Two bowel movements daily, which were whitish, dry, formed and offensive. Eczema increased spreading to chest and back as well as face. On account of the small gain of 2 ounces in one week, 2 ounces of milk was added and three days later 2 ounces more. The food mixture was Milk 19 ounces, barley water, 21 ounces, milk sugar 11 ounces giving an energy quotient of 126. The food strength was Fat, 19, proteid 19 and sugar 60. The number of feedings, quantity and intervals remained as before.

June 30. Weighed 11 pounds 11 ounces, a gain of 14 ounces in fourteen days.

The increase in food as often happens even when there was no previous gain increased the weight but brought on the catastrophe a diarrhea for ten days. For a time there were bowel movements every ten to fifteen minutes of a pale yellow curdled cheesy, sour and offensive character. Child was restless, slept little and cried much.

July 3. Baby was put on barley water for two days and the crying stopped and it slept well. Five ounces of milk were added with six to eight bowel movements daily resulting in a child was put on barley water for four days longer.

July 7. Weighed 11 pounds 6 ounces. The addition of milk produced the same bowel condition as before. It was 11 attempts to relieve conditions including (not fat free), the mother decided to

² Disturbances of Digestion in Infants Resulting from the Use of Too High Fat Percentages.

country and the further history is unknown. The child never had 2 per cent of fat, although $3\frac{1}{2}$ months old when the food disagreed, and was typically overfed on $1\frac{1}{2}$ per cent of fat.

The following case had less than 3 per cent of fat at 19 months, but had severe symptoms of overfeeding on an energy quotient of 140 from which she recovered at an incredible rate on less milk—later skimmed milk with very low energy quotient, gaining 5 pounds 14 ounces in 51 days, nearly 13 ounces a week for over seven weeks.

CASE 5—Baby McGuire (see chart)

August 20 Entered Wesley Hospital, 18 months old, had an enteritis of three weeks' standing, was thin, pale, haggard and

bowel movements were normal. On account of loss, the food was increased to milk, 35 ounces, barley water, 13 ounces, cane sugar, 1 ounce, fed as before, with the energy quotient 140.

September 21 Weighed 14 pounds on same food. One bowel movement daily, several days none, dry, pale, gray and hard. Child had not slept as well as before and showed eczema about the chest.

September 26 Weighed 14 pounds 12 ounces. Had gone home. The bowel movements were hard and dry, so that the child played with one, as with blocks, the eczema was worse. The same food mixture was given in five 10 ounce feedings at four hour intervals.

October 3 Weighed 14 pounds 1 ounce. Child had not taken food well since she went home and will only take a few ounces at a time. Had five or six bowel movements daily, always gray or whitish, these were at times hard and formed, again soft and cheesy. Never green. Child was cross and peevish and restless at night, but had no fever. The milk was cut down to 20 ounces, barley water, 20 ounces, cane sugar, $1\frac{1}{4}$ ounces, giving an energy quotient of 98.

October 10 Weighed 15 pounds 3 ounces, a gain of 1 pound 2 ounces in eight days. Had not been cross since the food was changed and took it well almost at once. Slept well and the diarrhea had stopped, but bowel movements are still a mass of whitish curds, the rest pale and yellow.

October 13 On account of the curds was put on straight skimmed (centrifuged) milk, 40 ounces, sugar, 1 ounce. Energy quotient of 75.

October 24 Weighed 15 pounds 10 ounces. Two good, yellow, normal bowel movements daily, no curds two days after being put on skimmed milk, the same food continued.

October 31 Weighed 17 pounds 5 ounces, a gain of 1 pound 11 ounces in one week. Energy quotient 66. Bowel movements normal.

November 7 Weighed 17 pounds 7 ounces. Still on the same food. On account of the small gain child was put on whole milk, 10 ounces, skimmed milk, 30 ounces, cane sugar, 1 ounce. Energy quotient, 80.

November 14 Weighed 18 pounds 5 ounces, a gain of 14 ounces in one week. Child had perfect digestion, good color, good disposition and slept well. Is getting solid, laughs and plays.

November 23 Weighed 19 pounds 15 ounces, a gain of 1 pound 10 ounces in nine days, on the same food. Energy quotient, 70. General condition excellent. Since this child went home it has received a small amount of additional food. I asked the mother many times as to just what this consisted of. She always stated positively that the child had one thin slice of bread about 2 inches square and a half cup of beef soup daily, and, every other day, she chewed a piece of meat the size of one half a finger. This child had been so sick that the mother had given her up, the latter had been cautioned so often and so hard against giving too much food, and her faith in the last milk was so implicit that I believe her statement is accurate. To make doubly sure I asked the nurse in charge of the diet kitchen to go to the home and investigate the matter. She was equally convinced that the child was getting no more than the mother stated. For a study in actual, rather than relative energy quotients, the caloric value of these could be added to the milk.

Such enormous gains are not so alarming nor do they carry the same therapeutic indication, as when whole milk is given, especially in excessive amounts. The offending fat is not present in sufficient amount to cause trouble.

From all that has been said I believe the inference is justifiable that overfeeding to the point of producing well-marked symptoms is not only widely prevalent in this country, but the rule. Our present methods, especially the percentage method, must then be inadequate to prevent this. If by one method—that of using simple milk dilutions with the addition of carbohydrates, and with no definite check on the total amount to be given, a 7 months' old child among our cases, whose food is in-

Case 5—Baby McGuire. Rapid gain on e. q. of 120 followed by loss. No gain for 3 weeks on e. q. of 140. Enormous gain on e. q. of 66 to 80. In general as e. q. is lowered gain is increased, and vice versa. Maximum gain of 1 lb 11 oz in one week on e. q. of about 70. Food at this time: Skimmed milk 40 oz, cane sugar 1 oz.

listless, with eyes sunken and a temperature of 101 F. Frequent green, curdy, slimy bowel movements. She was given stimulation and placed on cereal water for four days, then milk was added three ounces a day.

August 29 Weighed 12 pounds 13 ounces, bowel movements had been normal for several days, but had been losing to this time. Energy quotient was slowly raised to about 120. Food mixture consisted of: Milk, 25 ounces, cereal flour, malt, water, 23 ounces, cane sugar, $1\frac{1}{2}$ ounces. Six 8 ounce feedings were given daily at three-hour intervals.

September 5 Weighed 14 pounds 4 ounces, a gain of 23 ounces in seven days. Food was the same, with an energy quotient of about 100.

September 14 Weighed 14 pounds, with food as before,

creased from 10 to 15 ounces of milk can develop extensive eczema, restlessness, typical constipation, later diarrhea fever and loss in weight, then this method alone is not so accurate as it would be if combined with a procedure that would tell us in advance that that child's energy quotient was being sent up from a dangerous height of 130 to a disastrous one of 152. And if a "schedule for an average healthy infant (Holt) of 6 months calls for a fat 4, proteid 2, sugar 7 mixture of 30 to 48 oz. then that schedule is not even approximately safe in itself when it permits us to go from a proper energy quotient of 90 to a decidedly dangerous one of 145 if our healthy child weighs 16 pounds, as it ought to. These tables uniformly recommend excessive amounts and too short intervals that must lead to overfeeding unless we are familiar with the above picture of overfeeding and have had an unusual experience. The percentage alone is an unreliable and irrational check even in the healthy child. If we could have our cases under ideal control at all times we might be satisfied with recognizing symptoms of overfeeding as they arise. But with our conditions, especially in those of limited experience, something safer and more tangible is necessary—something that will forestall symptoms rather than permit us to recognize them. We have become convinced that in our feeding cases determination of energy quotient is simply indispensable. Those of us who have adopted it have become enthusiastic over it as we have over no other procedure in infant feeding. It is this point that I wish to emphasize especially, that this determination of energy quotient is not merely an interesting study in physiology, but an intensely practical procedure of the greatest value not alone to the scientific pediatrician, but to any man who feeds babies and wants to be sure of results. It alone enables him to tell approximately how much food his baby really needs, and by keeping this in mind, and departing from it only when clearly indicated, he will avoid on the one hand a prolonged underfeeding that is by no means uncommon and, on the other hand, a still more disastrous overfeeding.

It is true that caloric value represents only one function of food, that of heat production. It is equally true that in our overfeeding we have to do with a real milk overfeeding and that the amount of milk, and not the caloric value, would perhaps be the surest guide to the prevention of this symptom-complex. In a child at Wesley of 17 months and weighing 16 pounds that has been mentioned before, a change of milk from 26 oz. to 30 oz., but with an actual lowering of energy quotient from 96 to 90, due to lessening of sugar and barley water, produced nearly all of the symptoms of overfeeding within a few days. And yet these symptoms would doubtless have arisen with less increase of milk if the higher energy quotient had been maintained. These are theoretical considerations. For practical purposes the method advocated is amply sufficient and the most desirable one so long as we are all using well balanced but widely different food mixtures and need a common measure.

It need hardly be mentioned that this method is not to be used to the exclusion of other things. To feed a baby one needs all the help obtainable from every source. The baby itself must be seen; it must be weighed regularly and accurately; its disposition must be inquired into; its bowel movements must be seen, not alone described by the mother; the actual preparation of the food must be supervised. Nor is this method applicable only

to the simpler milk dilutions, plus carbohydrates, that we use. Its use is indicated nowhere so much as in the use of high fats in the conventional percentage method, for obvious reasons. Such indications for increase of food as apparent hunger, restlessness, failure to gain or loss in weight, or mere lapse of time, need hardly be discussed after what has been said.

The treatment of this condition, after it is present, is more or less evident from its pathogenesis. In general the fat must be reduced and the carbohydrates increased to take its place. In milder cases it is enough to do only the former, together with lengthening the interval to at least four hours. In severer cases the milk must be greatly reduced and a gruel or flour water added. If this is not sufficient to produce normal bowel movements and gain in weight, more sugar must be added, either as cane sugar, or preferably, according to Czerny and Keller, as maltose. Milk sugar has not shown itself serviceable clinically. To meet this one indication of overfeeding with milk Keller's *Malzsuppe*³ is intended. This or another combination of milk, flour and cane sugar or maltose, modified to meet the individual conditions, is best kept up for a number of weeks because these children are not readily lead back again to normal amounts of milk. The milk is then gradually increased and the carbohydrate diminished until the usual milk modification is again reached. Rapid improvement and ultimate cure are the rule.

We are handicapped in not having a desirable maltose or a serviceable malt preparation, in this country. The ordinary malt extracts can not be used in large amounts on account of their laxative action, and the use of maltose itself is not feasible. In some cases we have used for this purpose a well-known "baby food" that is composed largely of maltose, with excellent results.

In all of these cases, but especially in the severer ones the most rapid and certain *immediate* improvement is produced by the use of a fat-free milk as we would expect. I believe it is a matter of indifference whether this fat-free milk is sweet, i. e., skimmed milk, or whether it is buttermilk. So uniformly certain is the action of buttermilk in these cases, as in nearly all other digestive disturbances of infancy, that its well-deserved popularity is easily understood, and we can see why Baginski considers its use in dyspepsia for example, as "almost a specific, like antitoxin in diphtheria." After a considerable experience in the use of skimmed milk I am convinced that its action is the same as that of buttermilk, and that in both cases the striking results are due to the fact that we have a nearly fat-free food. If this is true then the use of skimmed milk has obvious advantages over that of buttermilk. It can be used in practically any strength, and is, of course best prepared with the addition of sugar, and often also of flour, or a gruel so that the absence of fat is compensated by the greater amount of carbohydrate in its place. The only objections to the use of skimmed milk in these cases of overfeeding are that it is rarely necessary to eliminate the fat so completely and secondly it is often difficult to return from a fat-free to a fat-rich food in a reasonable length of time. Constipation and curds in the bowel movements quite regularly follow the addition of even a small amount of whole milk i. e. of fat, and the change must usually be made very gradually.

³ Wheat flour 50 g. are stirred up in 271 of cow's milk and run through a sieve. In a separate tray 100 g. of Lecoult's Malzsuppen extract is dissolved in 60 g. of water. The two mixtures are then poured together and stirred until they are brought to a boil.

Just what part food intervals play in the production of overfeeding is difficult to estimate. Of the therapeutic value of longer intervals than the customary two or three hours there can be doubt only in the minds of those who have not tried it. If cow's milk does not leave the healthy baby's stomach before the end of $2\frac{1}{2}$ to 3 hours, and much later in the case of the sick one, then it would certainly seem indicated theoretically that the minimum interval should be 3 hours in health and 4 hours in pathologic conditions. A considerable and remarkably uniform experience has convinced us that the 4-hour interval is indicated in all pathologic cases and is preferable in all normal cases. Besides giving the stomach more rest and making the baby more comfortable, this long interval is a potent factor in preventing overfeeding, for it is manifestly more difficult to put enough food into a baby's stomach to overfeed it if that organ is filled only five or six times a day than if that process is repeated eight or ten times a day.

A word as to the ultimate results from feeding less fat. This consideration naturally limits itself to rickets and to the prevalent teaching as to its etiology, i. e., that these children get too little fat. There certainly is at the present time no real evidence that too small an amount of fat is an important factor in the causation of rickets, and there is an ever-increasing conviction that rickets can, and does, develop under our very eyes in spite of the fact that our cases are fed much fat—yes, often because of that fact (Holt and see babies O and F). Moreover, it is far from any one to recommend a small amount of fat. The child needs proportionately more of it early in the first year than at any other time in life, but that amount need never exceed an equal amount of proteid that the child can take with ease.

CONCLUSIONS

- 1 Overfeeding is so prevalent in this country that it is the rule.
 - 2 Overfeeding is second to no other factor in the pathogenesis of infant feeding.
 - 3 Overfeeding presents an easily recognizable, definite symptom-complex.
 - 4 The percentage method is inadequate to prevent overfeeding, the well-known feeding "schedules for an average healthy infant" of a given age fostering it by recommending excessive amounts, and, moreover, mere percentage leaves undetermined the amount of food the baby gets.
 - 5 To feed rationally and especially to prevent overfeeding it is necessary to know how much food the baby is getting in proportion to its body weight, best expressed in terms of energy quotient.
 - 6 The disturbing element in overfeeding with cow's milk is the fat.
 - 7 Fat in excessive amounts regularly produces constipation—proteids never do so.
 - 8 It is never necessary to give more fat than proteids of cow's milk.
 - 9 The interval between feedings should be 4 hours.

Rising by Another's Downfall.—A man may become grasping and avaricious, remarks the *Chicago Clinic*, even in the pursuit of knowledge, but when that avarice begins to work destruction to others, he becomes a menace to the general weal however virtuous his quest. No individual in the medical profession has the right to pursue any course for his own benefit which is carried on at the expense of others and with out their consent.

CHOICE OF METHODS FOR DILATING THE GRAVID UTERUS

EDWARD P. DAVIS, M.D.

PHILADELPHIA.

During the early months of gestation the induction of labor by gradual dilatation is not indicated. Circumstances arising which make the emptying of the uterus necessary, demand that this should be done as a surgical operation under anesthesia. Dilatation by graduated metal bougies, aided by bladed dilators and followed by curetting and gauze packing form the procedure most available in these cases. The indications for this procedure are pernicious nausea with fulminant toxemia, incomplete abortion, and hemorrhage from the uterus caused by or accompanying disease of the ovum. Gradual dilatation should be declined in these cases, because of the inefficiency of the gradual method and its danger of septic infection.

After the early months of gestation it may be necessary to dilate the uterus artificially for acute and threatened toxemia, placenta prævia and for the premature separation of the normally situated placenta.

IN TOXEMIA

In selecting indications for this procedure we must distinguish between the nephritis of pregnancy and acute toxemia of hepatic origin. The nephritis of pregnancy is not an indication for the rapid emptying of the uterus. These cases can be safely managed by other means. Should treatment not prove successful, placental changes will occur which will ultimately bring about the death of the fetus and be followed by its expulsion. Should treatment be successful, the mother may proceed to full term, while in some cases the treatment addressed to the condition results in exciting labor. The presence, then, of albumin in considerable quantity and of casts in the urine with symptoms of nephritis does not indicate a rapid emptying of the uterus.

When the patient has altered pulse tension, however, the nervous disturbances of toxemia, obstinate constipation and evidences of disintegration of the blood which accompany this condition, the uterus should be emptied as soon as is consistent with the patient's safety. Remembering the tendency to thrombosis and embolism and the hepatic congestion in these cases, that method must be selected which will do the least violence to the patient's tissues, thus avoiding the products of such violence which received into the circulation increase the danger of thrombosis and embolism in the viscera. For rapid dilatation of the uterus, in these cases, whenever possible, the hand should be the instrument of choice. If one finger can not be introduced, metal bougies or bladed dilators may be employed until one or two fingers can be inserted. Bimanual dilatation with one or more fingers of each hand working synchronously in opposite directions is, in my experience, the most efficient method. This may be carried to the point where the membranes may be ruptured and version performed, or the membranes ruptured and the forceps used for delivery. Should the cervix prove unmanageable by the fingers, in my experience, Bossi's dilator employed to one-half or two-thirds its full capacity during thirty to forty-five minutes with anesthesia has proven harmless and efficient. Except in rare cases, full dilatation with Bossi's dilator should be avoided, because of the danger of serious laceration. Should these methods not prove sufficient, incisions of the cervix have given good results.

Vaginal Cesarean section for acute toxemia or threat-

ened eclampsia is at present under wide discussion. I have not yet seen a case in which it was clearly indicated. In the hands of those accustomed to perform vaginal and abdominal section, this method may be available. It requires, however, assistants and technic which can not always be commanded. It is best available in well-equipped maternities. It is questionable whether the extensive dissection required in some of these cases would not add to the patient's danger.

In acute toxemia with threatened eclampsia, I have found elastic bags too slow in their action to be satisfactory. The continued pressure of these bags without anesthesia tends to excite eclamptic convulsions. Bags and bougies, in my experience, are contraindicated in this condition.

I desire to call attention to the fact that in a considerable number of cases of virulent toxemia with eclampsia, the patient is hopelessly ill when the physician is summoned. Beginning changes in the lungs, whether edematous or necrotic, forbid the use of anesthetics, and in these cases recovery under any form of treatment is exceedingly rare. The analogy between these cases and patients with extensive pneumococcus infection of the lung is close, and as the surgeon would hesitate to anesthetize a patient seriously ill with pneumonia, so he should avoid anesthesia and direct interference with a pregnant patient suffering from acute toxemia and eclampsia in whom pulmonary lesions are either beginning or well pronounced. Bleeding followed by saline transfusion, inhalation of oxygen and the very cautious use of veratrum, with rectal stimulation, give more hope of success.

Abdominal Cesarean section in acute toxemia with eclampsia is no more indicated than are other operations requiring anesthesia and incision and suture of the tissues.

IN PLACENTA PRÆVIA

In placenta prævia experience shows that the hand is far superior to any other instrument for dilatation. Until the operator is ready to proceed the use of the gauze tampon is indicated to lessen hemorrhage and prepare the way for dilatation. When, however, the necessary assistants and appliances are at hand, dilatation should be performed. In these cases the operator must use the hand in accordance with the conditions found on examination. When the placenta completely covers the os it must be perforated by the fingers, and if possible, a foot seized and brought down. Using the fetus as a plug the operator should not proceed to immediate delivery but promote gradual dilatation with the body of the child utilizing the opportunity to stimulate the mother. In cases in which the placenta does not completely cover the os, the membranes may be ruptured, cervix dilated and if the head be low down forceps may be applied and the child delivered. If the head is not engaged version may be selected. While the bimanual method of dilatation may be employed in placenta prævia in some cases it will be attended with more hemorrhage than dilatation by the one hand only.

While in some cases of placenta prævia the elastic bag may be useful its action as a rule is too slow and its liability to promote hemorrhage too great to bring it into direct comparison with the hand.

In my experience Bossi's dilator is an exceedingly dangerous instrument in placenta prævia. The cervix and lower uterine segment are so softened by the increased vascularity accompanying the condition that the tissues tear readily and often fatally. In a successful effort to

secure a living child in central placenta prævia I have seen the anterior portion of the lower uterine segment torn and the urethra ruptured.

Multiple incision of the cervix, vaginal Cesarean section or abdominal Cesarean section must be very rarely indicated in placenta prævia. Only in the well-equipped maternity and under exceptional circumstances, should these operations be chosen. While we must believe that cases of placenta prævia are sometimes seen in which the cervix is so hard as to be dilated with great difficulty, these cases must be exceedingly rare and should be exceptions to our rules of practice.

IN PREMATURE SEPARATION OF NORMALLY SITUATED PLACENTA

In premature separation of the normally implanted placenta immediate delivery is demanded. Here the thirty to forty-five minutes necessary for dilatation by Bossi's dilator or by the fingers is too long if a reasonably safe and quicker method is available. It is here that Cesarean section, vaginal or abdominal, under appropriate surroundings should be selected. In many cases the advantages would lie with vaginal Cesarean section, and consent may oftener be obtained for this operation than for the apparently more formidable one of abdominal Cesarean section. I believe, however, that in many cases the abdominal method will prove the safer.

In the hands of the physician not competent to perform Cesarean section, multiple incision of the cervix followed by introduction of the hand, rupture of the membranes and dilatation as rapidly as is consistent with the integrity of the mother's tissues should be chosen. With the patient in good condition, without excessive hemorrhage, the use of Bossi's dilator and the hand may prove sufficient.

The indications given for rapid dilatation of the uterus after viability comprise those most commonly seen. Occasionally, however, cases are observed in which threatened exhaustion or some serious pathologic condition in the mother demands rapid delivery. A labor apparently normal may proceed through its first stage and a portion of the second and exhaustion supervene. In these cases dilatation with Bossi's dilator, followed by complete dilatation with the hand under anesthesia, will permit the operator to proceed to immediate delivery by forceps or version.

IN COMPLICATED CASES

In patients whose pregnancy is complicated by cardiac lesion, impending death may demand immediate delivery. In these cases if the patient be in a hospital vaginal Cesarean section, incision of the cervix or dilatation by the fingers may be chosen. Occasionally, in phthisical patients, a similar choice must be made.

In the event of maternal death before delivery during labor, the fetus continuing to live and in fair condition, that method of delivery must be selected which is quickest. In my experience the advantages lie in abdominal Cesarean section in these cases.

In discussing so important a subject, I desire to make an earnest plea with the profession that complicated cases of labor be given their due importance. Medical science has now reached that stage of development when the general practitioner does not conduct a serious case of appendicitis or strangulated hernia without the aid of the surgeon. Complicated cases of labor are more difficult and more responsible than the one just cited. We should no longer advise method of treatment for these

cases because they can be carried out by the general practitioner any more than one would advise that a patient with appendicitis or strangulated hernia be deprived of operation and be given other treatment instead. It must be rare indeed for the general practitioner to be so situated that he can not obtain for a complicated case of labor the services of an obstetrician. Throughout the country there are so many well-equipped hospitals and facilities for transportation are so abundant that such cases, whenever possible, should be taken to hospitals and there receive adequate attention. If this is impossible, obstetricians have means at their disposal for establishing in private houses the aseptic technic which makes all surgical operations comparatively safe.

CONSIDERATION OF FETAL LIFE

I have said nothing concerning the consideration of fetal life. For example, in placenta prævia, often times the best results are obtained by sacrificing the child in the interests of the mother. When, however, the operator is so situated that he can perform any operation desired, and the parents express a strong wish that consideration be given the life of the fetus, this should not be neglected. Abdominal Cesarean section may sometimes be elected in deference to this consideration.

Clinical Notes

MULTIPLE ANEURISM OF THE AORTA, WITH RUPTURE INTO THE TRACHEA

PULMONARY TUBERCULOSIS SYMPTOMS SIMULATING PERICARDITIS*

AUGUSTUS A. ESHNER, M.D.

Professor of Clinical Medicine in the Philadelphia Polyclinic
 Physician to the Philadelphia Hospital Assistant Physician
 to the Philadelphia Orthopedic Hospital and Infirmary
 for Nervous Diseases

PHILADELPHIA.

History—An unmarried colored man, 32 years old, employed as a waiter, was admitted to the Polyclinic Hospital on account of severe cough, which had been present for four or five months, together with frequent expectoration of viscid mucoid material and pain in the side of the chest on coughing and on deep inspiration. His condition grew gradually worse, and five weeks before coming under observation he was compelled to give up work on account of persistent cough, weakness and loss of flesh. Four days before admission to the hospital he suddenly became much worse, with the development of pain in the back and the side and a feeling of compression in the precordium and shortness of breath, while the previous symptoms continued with increasing severity.

Examination—On admission the temperature was 98°, the pulse 112, the respirations 48. Respiration was labored and the expansion of the left side of the chest was obviously diminished, the portion below the clavicle moving scarcely at all. The percussion note was dull over the entire left chest anteriorly and posteriorly, with the exception of the lowermost portion anteriorly, and the breath sounds were greatly enfeebled throughout the entire area of dullness. The percussion note on the right side was clear while the breath sounds were intensified. Marked and forcible pulsation was visible in the fifth and sixth interspaces an inch or more outside the left nipple line, giving rise to bulging to an extraordinary degree. The area of cardiac percussion dullness was increased and the action of the heart was labored and the pulse weak. A systolic murmur was audible over the body of the heart near the pulmonary area, but no friction sound could be detected.

Shortly after admission an aspirating needle was introduced into the left eighth interspace in the midscapular line and four

ounces of amber colored fluid were withdrawn. The apparatus working badly at this time, the needle was again introduced several hours later and four ounces of blood stained fluid were obtained. The fluid was straw colored and had a neutral reaction and a specific gravity of 1018. It contained a large amount of albumin and chlorids, and a slight coagulum formed at the bottom of the containing vessel. In the sediment obtained by centrifugation and treated with Wright's stain only granular debris was found. The hemoglobin percentage was 80, and the number of red blood corpuscles 4,100,000, the number of colorless corpuscles 13,200 in the cubic millimeter. The patient gained no immediate relief from these procedures, although in the sitting posture the percussion note over the upper portion of the left chest just below the clavicle appeared clearer and the breath sounds more distinct.

Diagnosis and Treatment—The presence of acute dilatation of the left side of the heart was suspected, while Dr. Riesman, who was good enough to see the patient with me, suggested that the overaction of the heart, with the bulging apex beat and the disproportionately weak pulse, might represent untoward effects of the action of digitalis, which at this time we did not know had actually been administered. Spirit of glonoin, 1 minim, and spirit of nitrous ether, 1 fluidram, were given every hour and tincture of aconite, 1 minim, every two hours for six doses, with the result that the heart grew quieter and the apex beat receded and became less marked. The patient passed a fairly comfortable night, although he slept but little and complained of pain radiating from the left shoulder to the precordium. The urine had a specific gravity of 1032 and contained a trace of albumin, with urates, but no sugar or tube casts.

Further History—There was little change in the physical signs on the succeeding days, but the temperature began to rise on the second day, gradually reaching 103.2 on the third day. The pulse ranged between 96 and 128 and the respirations between 28 and 48. At this time it was noticed that eating appeared to induce coughing and this, in turn, vomiting. Previously, coughing had been quite unobserved, but now it became marked and the expectorated matter contained a slight admixture of blood. The percussion note became clearer over the upper half of the left chest, with roughened breathing and mucous râles, while dullness persisted over the lower half, with enfeebled breath sounds. Vocal resonance and fremitus were diminished in lesser degree above than below. The hemoglobin percentage was found to be 96 per cent, the number of red blood corpuscles 5,050,000, the number of colorless corpuscles 11,800 in the cubic millimeter.

On the fourth day it was noted that the patient complained of severe precordial pain occurring in paroxysms. He exhibited a preference to lie on the left side. Morphine was administered hypodermically to secure sleep at night, but it produced only quiet. On the fifth day an aspirating needle was introduced into the pericardial sac but only a small amount of blood was withdrawn. The impulse of the heart was less pronounced and a to and fro murmur could be heard over the body of the organ. The hemoglobin percentage at this time was 80 and the number of red corpuscles 4,100,000 and the number of colorless corpuscles 13,200 in the cubic millimeter.

On the sixth day coarse crackling was noted at the end of inspiration. The apex of the heart was now in the fourth interspace. The patient was readily exhausted by any exertion, active or passive. The sputum was greenish yellow in color and thick and tenacious in consistency. It contained no lumpy or cheesy particles and no fibrinous casts. Microscopically pus corpuscles, diplococci and staphylococci were found, together with a few rhomboidal crystals, but no tubercle bacilli. On the seventh day the urine had a specific gravity of 1024, and was free from albumin, sugar and bile. It contained a trace of indican and occasional hyaline tube cast cylindroids, mucus, urates, leucocytes and epithelial cells. It failed to yield the diazo reaction.

On the ninth day it is recorded that the percussion note on the left side of the chest was hyperresonant from the clavicle down to the third interspace. From here to the fourth interspace the note was mixed and below this it was dull. The apex

* Read before the Section on General Medicine of the College of Physicians of Philadelphia Feb. 11 1907.

beat of the heart was visible in the fourth interspace in the parasternal line and here a to and fro rub was palpable and a marked to and fro friction murmur was audible. There was considerable cough, with blood tinged sputum. Bronchial breathing could be heard over the base of the left lung from the angle of the scapula downward, together with small moist râles. On the eleventh day the patient was comfortable and free from pain. Respiration was easier and the man slept well at night without anodyne or hypnotic, although he continued weak.

On the twelfth day the apex beat was most distinct in the fourth interspace one half inch within the nipple line and in the fifth interspace 1 inch within the nipple line. On the thirteenth day the friction sound was much less audible over the heart and an occasional click was audible at the end of the systole. On the fifteenth day the urine exhibited no abnormality. On the following day the friction sound was no longer audible with the action of the heart, although appreciable with inspiration at and beyond the apex. Sonorous and sibilant râles with roughened breathing could be heard over the right chest anteriorly, with crackling râles posteriorly. On the left the breath sounds were clear above, while below the angle of the scapula fine crepitation was audible and below this blowing breathing, with crepitation. On the eighteenth day the first sound of the heart was dull at the apex and attended with a rough murmur in the second and third interspaces slightly to the left of the sternum where also occasional crackling was audible. On the next day the patient was comfortable, taking food well, sleeping soundly at night, breathing with difficulty and coughing less.

Death—The conditions described continued for three days, when without premonition the patient was seized with dyspnea and an attack of cough, resulting in the expectoration of about $1\frac{1}{2}$ pints of blood, and within two minutes the man was dead. The urine had, on the day previously, again been found normal. The temperature had pursued an irregular course, with a somewhat declining tendency, in the afternoon ranging between 103.2° on the third day and 100° on the twenty first day and in the morning between 101.8° on the fourth day and 98.4° on the day of death. In the last six days of life it had fluctuated between 98.6° and 101.6° . The pulse had fallen from 136 on the third day to 88 on the day preceding death, and the respirations from 52 to 24.

Previous History—The patient had had measles, whooping cough, chicken pox and diphtheria in childhood and an attack of left sided pneumonia at the age of 16. At 27 or 28 he suffered for eight months with an infected wound of the leg following a punctured wound of the foot inflicted by a nail. Two operations were required an anesthetic not being given in the second on account of the presence of a cardiac lesion. At the age of 29 the man had been treated for an affection of the mitral valve. He drank whisky rather freely and smoked little. He had had three or four attacks of gonorrhea, the last one year before coming under observation. He had a chancre at the age of 27, followed by a general cutaneous rash.

Postmortem Examination—The left pleural cavity was found to contain 350 c.c. of straw colored fluid. The left lung was bound to the chest wall from the anterior axillary line backward to the vertebral column by recent fibrinous adhesions that were readily broken up, the apex was bound by dense, resistant adhesions. The right pleural cavity was free from both fluid and adhesions.

The pericardium was not adherent to the pleura. The pericardial sac contained about 6 c.c. of straw colored fluid. Its parietal surface was smooth, grayish white and glistening. The visceral layer also was smooth and glistening. On its anterior aspect it presented an area 4 cm long and 1.5 cm wide, deep purple in color, while directly opposite on the parietal layer was an area 1 cm long and 1.5 cm wide of deep red color. Both lungs were constituted of three lobes. The lower and median lobes of the left lung were solid while the upper lobe, though somewhat collapsed and nodular at the apex, contained a certain amount of air. On section the lower lobe, especially at the center, was the seat of a large number

of confluent tubercles, becoming progressively less dense toward the periphery. A similar condition was present in the middle lobe and, perhaps in less marked degree, at the apex and base of the upper lobe. Portions of the apex contained inspissated mucoid or cheesy masses. The lower lobe of the right lung on section appeared stained a deep blood red and gentle pressure caused the escape of frothy mucus. A similar condition was present in the middle and upper lobes. The apex was the seat of a small number of whitish blue, apparently subpleural nodules. Both lungs exhibited marked pigmentation, some what irregularly distributed, and in places apparently following the boundaries of the lobules.

The spleen was flattened, apparently somewhat enlarged, dark red in color, flabby in consistency and on section rather friable.

The liver was large and firm presenting a somewhat mottled appearance on section. The gall bladder was normal.

The kidneys were large, pale and fatty, with lines of hyperemia. The capsules stripped readily, leaving behind a smooth surface.

The heart was comparatively small, its valves and cavities normal. The leaflets of the aortic valve were the seat of slightly opaque atheromatous change. The arch of the aorta below and toward the right exhibited an aneurismal dilatation admitting the little finger for a distance of 2 cm. At a distance of 1 cm to the left of this was a second dilatation of much the same size, which had eroded the trachea and ruptured into its lumen. Somewhat farther to the left was a third aneurismal dilatation large enough to admit the thumb for a distance of 1.5 cm and partly filled with laminated clot. A fourth aneurism arose from the thoracic aorta, about 3.5 cm below the arch. This was 7 cm long, 5 cm thick and 4 cm wide. It was filled with friable clot. A fifth aneurismal sac, 1.4 cm long, arose at a slightly lower level and extended down to the diaphragm. The esophagus passed beneath the arch of the aorta to the right of the first and the latter two aneurisms and obliquely forward and upward and to the left over the surface of the second.

Microscopic Examination—Dr Guthrie McConnell examined the lung tissues. Small scattered areas were found apparently quite devoid of alveolar structure, which was replaced by tissue composed of cells containing epithelioid nuclei, lymphocytes and connective tissue. Some portions of these areas were degenerated, as indicated by the granular appearance and the diffuse staining. The alveoli generally were filled with aluminoid exudation containing numerous erythrocytes. The liver exhibited little change other than slight hyperemia around the central vein of some of the lobules.

The spleen exhibited some increase in connective tissue of the trabeculae and slight congestion. The lymph nodes were prominent.

In the kidneys the cortical tubules exhibited marked cloudy swelling of the epithelium, absence of nuclei and granular deposits within the tubules. The glomeruli in places were congested. In one area a glomerulus was replaced by connective tissue, which also involved adjacent structures. There was also round cell infiltration in areas.

The case was at first looked on as one of pleural effusion, which it was thought might be due to the dilatation of the heart that appeared to be present. The extraordinary bulging of the apex, in conjunction with the labored action of the heart, and the disproportionately small and feeble pulse, was, as stated though possibly due to the excessive action of digitalis. With the development of systolic and diastolic friction sounds over the heart the existence of pericarditis could not be excluded but puncture failed to disclose the presence of an effusion into the pericardial sac. Somewhat later still as the temperature rose and the sputum became blood streaked and crepitant râles made their appearance the possibility of pneumonia had to be taken into consideration and the progressive improvement both objectively and subjectively around the gradual resolution of the morbid process.

to confess that aneurism was not even suspected. Perhaps an x-ray examination would have disclosed its presence, but in view of the situation with relation to the heart of the largest dilatation of the aorta and the inconsiderable dimensions of the others, reasonable doubt may exist as to this point. The fatal hemorrhage and the result of the postmortem examination were wholly unexpected. Tuberculosis of the lungs had been suspected, but tubercle bacilli could not be found in the sputum during life. We felt quite convinced that pericarditis was present, but of this there was no anatomic trace.

Although the diagnosis was thus entirely at fault, we may comfort ourselves with the thought that at least the treatment employed did no harm, but, on the contrary, so far as this was possible, the rest in the recumbent posture, together with the administration of drugs having the power of lowering arterial tension and of diminishing the work of the heart, seemed to do symptomatic good. It may, however, be admitted in view of the conditions found at autopsy that the puncture of the pericardium was not wholly free from danger.

GUNSHOT WOUNDS INFECTED WITH THE BACILLUS OF MALIGNANT EDEMA.

REPORT OF TWO CASES, OPERATION, RECOVERY OF ONE
G. H. R. GOSMAN, M.D.

AND
A. W. WILLIAMS, M.D.
Captains and Assistant Surgeons, U. S. Army
CAMP DOWNES, LEYTE, P. I.

CASE 1—Patient—Private Hilario Sajes, Philippine constabulary, a native of the Island of Leyte.

History—The patient was brought into Camp Downes to the Military Hospital on the night of Jan. 8, 1907, suffering from gunshot wounds caused by slugs projected from a native cannon (a lantaka¹). The injuries had been sustained two days before admission to the hospital as the result of an encounter with pulajanes.

Examination—Two wounds were found, the first, 4 by 2 cm. in size, had its entrance in the dorsum of the right hand, no exit, the second had its point of entrance, 3 by 2 cm. in size, on the anterior surface of the right wrist.

Treatment—The wounds were thoroughly cleaned and wet dressings (1:2000 hot mercury bichlorid) applied. On the following day a bluish discoloration extended over the hand, the warmth of the member (circulation) was still maintained. On the second day multiple incisions were made with the object of evacuating pus. On introducing the hypodermic needle to inject cocaine for local anesthesia the pressure within very promptly forced the piston of the syringe back, filling the barrel of the syringe with gas. On withdrawing the needle the gas sizzed out of the tissues. No pus escaped from the incisions made in the tissues, only blood, serum and gas. On the third day the thumb which was gangrenous was amputated and the muscles and subcutaneous tissues of the entire hand were found to be gangrenous. Microscopic examination of a smear of serum from the tissues, stained with methylene blue, showed numerous bacilli, many of which showed spores, the pointed rods appearing at either end of the spores. Several specimens emphasized the appearance of these spore-bearing bacilli.

Diagnosis—The infection was diagnosed as one of malignant edema and was confirmed by a characteristic growth in stab cultures of nutrient agar. The infection could be traced by

¹ A lantaka is a cannon made of gas pipe or iron piping of larger caliber, old Spanish cannon etc., mounted on wheels or hauled by hand or lashed to a tree. For combustion match heads are usually used, numerous slugs, chain-nails, screws and rocks are the projectiles. A fuse ignites the match heads through a tube.

the dilated blue superficial veins and swollen arm (one-third larger than normal) to a point two thirds the distance up the arm.

Operation—A modified circular amputation was done, disarticulating at the shoulder joint. An examination of a smear made from the tissues at this point was negative for the bacillus of malignant edema. The patient's temperature, which had ranged from 103 to 104 F., promptly subsided to normal and an uneventful recovery ensued.

CASE 2—Patient—Delfalio Marcello, volunteer (volunteer against the pulajanes), also a native of the Island of Leyte.

History—Similar in every respect to that of Case 1. The two men were brought in together.

Examination—The patient had a gunshot wound of the left leg. The wound of entrance was 2 cm. in diameter and located on the outer side of the upper third of the leg, the wound of exit, 3 cm. in diameter, was on the inner aspect of the leg. A bluish discoloration of the leg extended to the knee-joint and a strong odor of decomposition was present. From the knee joint down the leg was swollen and cold. There was a lacerated gunshot wound, 12 by 8 cm., on the inner surface of the right thigh.

Treatment—Hot local applications and rectal injections of strong coffee were administered during the night. On the following morning the patient's general condition was bad, with no return of circulation in the leg.

Operation—Amputation above the knee joint was decided on. On incising the skin and subcutaneous tissues a crackling sound and a retraction of the skin were very marked. This crackling was likewise apparent as the muscles were divided showing that a gas bacillus was undoubtedly present. No microscopic examination or culture was made. The patient succumbed at the commencement of operation.

Just how these patients became infected with the bacillus of malignant edema is not known, but, as they were in the mountains in rain and dirt for several days, it is believed they must be cases of infection from dirt. The probability of the bullets having been infected must be considered.

VERONAL DERMATITIS

WILLIAM HOUSE, M.D.
PORTLAND, ORE.

In a search of the literature at my command I have been unable to find a record of any case of dermatitis due to veronal, although a number of deaths from large doses, two hundred and fifty grains or more, have been reported. I have observed a considerable number of cases of drug eruption from copaiba, quinin, iodoform, iodids, bromids, and one from chlorid of gold and soda, but in no instance have I seen any eruption as acute and extensive as in the case here described.

Veronal is being extensively used. It is said to be efficient in doses of seven to ten grains, but I have used it repeatedly in fifteen-grain doses for insomnia. In subacute mania I have given ten grains every three hours, and in acute alcoholism single doses of twenty grains. In these and other cases in institution work I have prescribed, or seen prescribed by my colleague, R. L. Gillespie, about sixty ounces of veronal. No unpleasant effects have been witnessed, except vertigo, until the following case occurred.

Patient—D. P., retired merchant, aged 61, suffering from subacute melancholia.

History—I first saw him at 1 a. m., February 10, on his arrival after an all day car ride. He was tired and nervous and complained of inability to sleep. He was given 15 grains of veronal. He seemed to recognize it by the taste, and declared he had taken it before and it had poisoned him. Inasmuch as he had been taking for months all kinds of nerve sedatives, this suggests a peculiar sensitiveness of taste for the drug, perhaps

part of his idiosyncrasy. At the time the remark was construed as a delusion. After taking the medicine he passed a restless night. On visiting his room in the morning I found him sleeping soundly. When aroused he complained of stupor and vertigo. His body, which on retiring exhibited no dermal abnormality, was found to be covered with an extensive eruption symmetrically distributed. The face appeared red, swollen and congested. On the back of the thorax the skin was hyperemic and tense, as in severe scarlet fever, and appeared as angry as does erysipelas. The front of the body and the arms and legs presented an eruption of blotches ranging in size from a quarter to a half dollar, separated by spaces averaging an inch. The center of each was a dark red papule, surrounded by a less intense raised area shading rather sharply into normal skin. The whole appearance was that of a severe bee sting or spider bite. Most of the blotches were circular in outline on the body and oval on the limbs, the long axes corresponding to the long axes of the limbs. About the axillæ the eruption was absent, the skin, by contrast, appearing curiously white. The itching was intense. At 3 p. m. the temperature had risen to 103 F, the pulse to 112, and the general appearance of the patient suggested severe toxemia. The temperature subsided to 99 F by the following morning, rising to 100 F in the afternoon, and returning to normal the next day. Meanwhile, the rash and toxic symptoms gradually disappeared, so that all that remained were a number of small petechiæ marking the sites of the larger lesions.

The cause of the dermatitis is verified by the statement of his former physician, that he had witnessed a similar eruption and toxemia in this patient after giving him five grains of veronal and repeating it in three hours. The significance of the eruption was not grasped until it occurred for the second time under medical observation. The patient also assures us that he took the same drug at a still earlier period with identical results.

THE NEGLECT OF THE ANAMNESIS

BAYARD HOLMES, B.S., M.D.

CHICAGO

Fashion is inexorable. The movements of the human mind in the form of public opinion and public action are like the tides. At one time a whole nation seems to be moved by a propulsive insanity and they trek to a new country or a new shrine. Again the sea calls and in every gulf and along every coast creep the galleys and blanders of the adventurers. In a century Europe was suddenly covered with useless and meaningless towers that later furnished an almost inexhaustible supply of building material for the masonry of another period. While Athens was a city of thatched hovels and skin clad warriors a race was born that produced an imperishable art and an almost indestructible architecture. A new world was discovered in one century and in another America was subdued and contracted by an interminable net work of iron roads. In medicine the same phenomena are observed. Pathology grew out of empiric medicine in the Fifties and in the Eighties antiseptic surgery and bacteriologic pathology sweep the remnants of the old empiricism and the old pathology aside and the literature of medicine was rewritten.

It is hopeless indeed to attempt to turn these ocean currents of the mind these tides of human activity, to call a halt in the unreasonable flow of energy in the direction which it unthinkingly takes. The successful man and the time server go with the current the philosopher looks on with regret and the impetuous youth struggles against the invincible. The undue attention which the medical curriculum gives laboratory study and microscopic investigation impresses the student with an exaggerated sense of the importance of the evidence they afford. The result has been a dangerous neglect of the study of the clinical history by our younger men and a great loss in the wisdom as compared to the knowledge of the resulting doctor. The patient

is and always will be worthy of more study than the disease, and his recovery and not the diagnosis is his need and the duty of the doctor. Our medical ancestors knew this. A few of us hiding behind some protecting buttress to escape the frenzied horde of diagnosticians with their armament of microscopes, ophthalmoscopes, laryngoscopes, cystoscopes, and proctoscopes still believe it.

Thirty years ago the medical schools of the United States furnished but little laboratory teaching. The first meddling work which the author did in the curriculum of the college to which he was attached was to extend very greatly the laboratory method and to tax his faculty with fifty thousand dollars for buildings and equipment, to double the faculty with an army of laboratory teachers, and to add to the burdens of the student a year or two of time. This extension proved fashionable, while the coincident clinical and literary courses were never realized. All other medical schools followed with enormous laboratories and extensive laboratory courses. But to the profession these methods have proved disappointing. They monopolize the time of the student, they disparage the study of the history of the patient and all clinical observation and they utterly neglect the medical literature and send out the young doctor with a distorted sense of the probability of disease ignorant of the experience of medicine, and armed with impedimenta of prejudice and paraphernalia of diagnostic instruments and wholly out of sympathy with the profession whose emoluments he would divide, and ignorant of the life of the community on whom he expects to subsist. All this is attested by the proceedings of our medical societies, by the columns of our medical press and by the bag of instruments of our young medical men, and by their utter disregard of any sense of responsibility to cure the patient.

Far be it from me to disparage microscopy, enteroscopy, or even cryoscopy, but the value of the anamnesis and the immeasurable and prepondering reliability of the evidence of the master sense of touch can not safely be discredited or denied. The reader may never know the full meaning of this until personal misfortune overtakes him or his and he calls on the laboratory physician for help and finds him, hound like, searching out with his cold and sharp nosed instruments, the stirrer up of disease utterly regardless of the patient's need of physical support. Then will he value less highly the product of this method which is plainly marked, "made in Germany" and might be marked because it does not fairly represent the best Teutonic product, "for exportation only." Then will appear most forcibly the truth of the Hippocratic adage "It is the duty of the doctor to cure his patient." Our education should strive to produce less of a laboratory man than a diagnostician less of a diagnostician than a doctor, and less of a doctor than a fellowman.

104 East Fortieth Street

Sign of Suprarenal and Meningeal Disturbance. The White Line—Sergeant announced in 1903 that he had had occasion to observe a condition simulating meningitis in a young girl, but autopsy revealed complete cheesy degeneration of both suprarenal capsules while the meninges were intact. A white line appeared when the finger nail was drawn across the abdomen of the patient and lasted for two to five minutes. He has since noted this white line in a number of other cases in which the suprarenals were primarily or secondarily affected and others have confirmed his observation. Sergeant has never observed the white line with an arterial pressure above 12 (Pottam). It disappears on administration of adrenalin and is evidently due to reflex spasm of the capillaries during low arterial tension with more or less dilatation of the vessels. The subject was discussed at the meeting of the Paris Society Med des H p in February at which some cases of the suprarenal pseudo meningitis were reported as also two cases of resolution in which the white line or a partially red line was noticed. In both the latter cases lumbar puncture with removal of 20 cc of fluid had a marked beneficial effect especially on the headache. The fluid was opaque but not turbid but unrecognizable for a

PRESSURE CLAMP FOR LATERAL ANASTOMOSIS

PRELIMINARY REPORT

WILLIAM SENN, M.D.

CHICAGO

This appliance consists of a base bar $2\frac{1}{8}$ inches long, with cross-arms one inch in length, hinged at the center point of the bar and so arranged as to be forced down on the base by means of a spring causing pressure of about four pounds to the inch. When opened the clamp is cruciform, when the cross-arms are closed the clamp has a width of $\frac{3}{8}$ inch and a thickness of $\frac{3}{16}$ inch. Figure 1 shows the alternate arms partially closed.

The clamp is applied as follows. The surfaces to be approximated having been brought in apposition, the walls are punctured down to the mucous membrane ($\frac{1}{8}$ inch incision), the opened cross-arms are forced through mucous membrane into the lumen of the bowel and, with a flat probe or like instrument, used as a wedge, the cross-arms are spread and closed on the base bar, as a knife blade is closed, leaving intestinal wall between

the closed cross-arm and the base bar. The opposite cross-arms are similarly inserted into the opposing organ and closed in a like manner. A continuous Lembert suture is then applied if time permits, enclosing the clamp, which is left to slough through in a manner similar to that when a McGraw ligature is applied. This procedure is illustrated in Figure 2, the cross-arms being inserted, but not closed. Figure 3 shows anastomosis completed.

Experiments on dogs have shown that the clamp sloughs through in about seven days. An opening was left between the stomach and duodenum about 2 inches in diameter. Union was perfect leaving a smooth mucous lining approximation complete.

100 State Street

THE CLIMATE OF SOUTHERN MAINE IN THE TREATMENT OF THE LATER STAGES OF HYPERTONIA VASORUM

LOUIS FAUGERES BISHOP, M.D.

NEW YORK CITY

The climate of southern Maine during the summer months is decidedly bracing in character, and has many advantages in the treatment of diseases of the circulation which have developed as a result of mental overwork and worry in persons otherwise healthy. These patients we sometimes speak of as cases of secondary low arterial tension, because they are suffering from a failure of the circulation secondary to vascular strain. It is, however, better to speak of them as the later stages of hypertonia vasorum, because so many while suffering from the effects of a failing circulation, nevertheless, do not exhibit at all times the low tension to which they have a strong tendency. Increased or excessive vessel tone has its origin in other conditions than organic disease of the kidneys or blood vessels.

Hypertonia vasorum of nervous origin is a distinctly modern disease, and although it has been noticed by older writers it has never been given the prominence it deserves. Patients suffering from this malady, as the result of mental strain and worry, show signs much of the time of a chronic high tension in the arteries. This is followed by cardiac hypertrophy and the train of symptoms which we all as clinicians have so often observed.

To understand how this comes about it is necessary to recognize the existence of a tone-maintaining function of the central nervous system that is constantly exercised over the peripheral circulation. If such a force did not exist the blood would immediately settle to the dependent portions of the body, dilating the blood vessels, and the circulation as such would cease to exist. But any undue strain on the nervous system leads to an over-activity of this tone-maintaining function and finally develops a chronic overtone, which makes it difficult for the blood to circulate and wears out the heart by increasing resistance. Consequently there develop irregularities in the circulation and damage to the blood vessels, which frequently lead to accidents in the brain, followed by paralytic symptoms. I have seen a number of such patients presenting dilatation of the heart, general debility with decided weakness of one arm and leg, and even fairly marked aphasia, make very satisfactory progress toward recovery during a single summer on the coast of southern Maine.

My observations were made during summer practice at York Harbor. Here the climate in summer is an unusual combination of coolness and dryness. The coast recedes so that the fogs, which are so troublesome in northern Maine and even in Rhode Island, are not frequent. The soil is such that in a short time after a rainfall it is entirely dry. Excessive heat in summer is almost unknown. The summer climate in Maine, as affording a pleasurable existence to the sojourner in hot weather is too well known to need commendation here but its importance as a health resort, especially for this particular class of invalids—that is of brain workers who are suffering from disorders of the circulation—should be much better known.

Free Dispensary Abuse.—The trustees of our medical charities can check the abuse by enforcing the payment of adequate fees by private ward patients and by careful investigation of out patients.—G. W. GAY, Boston.

New and Non-Official Remedies

THE FOLLOWING ARTICLES HAVE BEEN TENTATIVELY ACCEPTED BY THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR INCLUSION IN THE PROPOSED ANNUAL, "NEW AND NON-OFFICIAL REMEDIES." THEIR ACCEPTANCE HAS BEEN BASED LARGELY ON EVIDENCE SUPPLIED BY THE MANUFACTURER OR HIS AGENT, BUT TO SOME EXTENT ON INVESTIGATION MADE BY OR UNDER THE DIRECTION OF THE COUNCIL. CRITICISMS AND CORRECTIONS ARE ASKED FOR TO AID IN THE REVISION OF THE MATTER BEFORE FINAL ACCEPTANCE AND PUBLICATION IN BOOK FORM.

THE COUNCIL DESIRES PHYSICIANS TO UNDERSTAND THAT THE ACCEPTANCE OF AN ARTICLE DOES NOT NECESSARILY MEAN A RECOMMENDATION, BUT THAT SO FAR AS KNOWN IT COMPLIES WITH THE RULES ADOPTED BY THE COUNCIL.

W. A. PUCKNER, SECRETARY

(A list of all accepted articles is published on one of the advertising pages of *The Journal* in the first issue of each month.)

(Continued from page 1185)

AKARALGIA

GRANULAR EFFERVESCENT SODIUM SALICYLATE COMPOUND—MERRELL.

A mixture each 8 Gm. (2 drams) or which is said to represent sodium sulphate 2 Gm. (30 grains), sodium salicylate (Merrell) 0.6 Gm. (10 grains), magnesium sulphate 3.3 Gm. (50 grains), lithium benzoate 0.3 Gm. (5 grains) and tincture of nuxvomica 0.4 Cc. (8 minims).

Dosage—8 Gm. (2 drams) in 120 Cc. (4 ounces) of water, one-half hour before meals, in acute cases one dose every two or three hours until relieved.

Prepared by Wm. S. Merrell Chemical Co. Cincinnati, Ohio.

ANTISEPTIC—Credé

A name applied to Silver Citrate, which see.

Manufactured by Fabrik von Heyden, Radebeul, near Dresden, Germany (Schering & Glatz, New York).

DOLOMOL

Dolomol is magnesium stearate $Mg(C_{18}H_{35}O_2)_2$, containing small amounts of magnesium palmitate and oleate.

It is a white powder insoluble in water, unctuous to the touch, nearly odorless and tasteless. It is claimed to be practically free from oleate. Its magnesium content corresponds to nearly 7 per cent. MgO.

Action, Uses and Dosage—Acting as a protective to the skin, Dolomol is recommended in cutaneous affections as a dusting powder, alone or mixed with various remedies.

The following dolomol compounds are listed: Dolomol Acetanilid, 25 per cent.; Dolomol Acid Boric, 20 per cent.; Dolomol Acid Carbolic, 5 per cent.; Dolomol Acid Picric, 25 per cent.; Dolomol Acid Pyrogallic, 5 per cent.; Dolomol Acid Salicylic, 5 per cent.; Dolomol Acid Salicylic, 10 per cent.; Dolomol Acid Tannic, 10 per cent.; Dolomol Alum, 10 per cent.; Dolomol Aristol, 10 per cent.; Dolomol Balsam Peru, 10 per cent.; Dolomol Bismuth Subgallate, 25 per cent.; Dolomol Calendula, 25 per cent.; Dolomol Calomel, 25 per cent.; Dolomol Camphor, 10 per cent.; Dolomol Chrysarobin, 5 per cent.; Dolomol Euphorphen, 10 per cent.; Dolomol Gualacal, 5 per cent.; Dolomol Ichthol, 10 per cent.; Dolomol Iodoform Deodorant, 10 per cent.; Dolomol Menthol, 5 per cent.; Dolomol Naphthol, 5 per cent.; Dolomol Oil of Cade, 10 per cent.; Dolomol Resorcin, 10 per cent.; Dolomol Salol, 10 per cent.; Dolomol Sulphur Sub., 25 per cent.; Dolomol Tar, 10 per cent.; Dolomol Thymol, 2 per cent.

Manufactured by Pulvula Chemical Co., New York. Not patented or trademarked.

ELIXIR OF ENZYMES

Elixir of enzymes is a solution containing pepsin and rennet in a menstruum containing 20 per cent. of alcohol.

Elixir of enzymes is a light yellow palatable liquid preparation. One part digests about 20 parts of coagulated egg albumin in 2½ hours. Eight Cc. (2 fluidrams) coagulate 500 Cc. (one pint) of milk in a few minutes.

Actions and Uses—It is claimed to be useful as an aid to digestion and as a vehicle for various drugs.

Dosage—1 to 8 Cc. (1 to 2 fluidrams) with meals, children in proportion.

Manufactured by Armour & Co., Chicago.

LUBRASEPTIC

Lubraseptic is a jelly prepared from Chondrus (Irish moss) containing 2 per cent. boric acid and 0.067 per cent. formaldehyde.

The material is packed in screw cap metal tubes and sterilized by heat.

Lubraseptic is a colorless transparent jelly almost completely soluble in water. It is claimed to be absolutely sterile.

Actions and Uses—Lubraseptic is said to be a disinfectant which is non-irritating to the skin or mucous membranes.

It is claimed to be useful as a lubricant for the fingers or for surgical instruments and as a dressing for burns, abrasions and slight lesions.

Dosage—It is put up in collapsible tubes and it is suggested to reject the portion first expressed to make sure of the sterile condition of that used.

Prepared by Russell & Lawrie, Tarrytown, N. Y.

PERHYDROL

THIRTY PER CENT SOLUTION OF HYDROGEN DIOXIDE

Perhydrol is a 30 per cent. solution of hydrogen dioxide which is free from acid.

While perhydrol is stable, dilutions of perhydrol rapidly deteriorate unless they are preserved by the addition of some acid.

Actions and Uses—By suitable dilution a preparation is obtained equivalent to the official solution of hydrogen dioxide. An advantage is claimed for this preparation that it is less irritating on account of the absence of acid. The full strength preparation is said to be useful as an application to nevi, ulcers, gummata, etc. Diluted one-half to two-thirds, it may be applied to syphilitic ulcers, gangrenous processes, ulcerating buboes, in endometritis, suppuration of the middle ear, etc.

Manufactured by E. Merck, Darmstadt (Merck & Co., New York). U. S. trademark No. 44147.

PHENOLPHTHALEIN

is a product of the interaction of phenol and phthalic anhydride.

It may be prepared by heating together 10 parts of phenol, 5 parts of phthalic anhydride and 4 parts of concentrated sulphuric acid for 10 to 12 hours at 115 to 120° C. (230 to 245° F.). The product of the reaction is boiled with water and the residue dissolved in soda lye. From this solution the phenolphthalein is precipitated by the addition of acetic acid. The precipitate after washing is dissolved in six times its weight of absolute alcohol and the solution decolorized by animal charcoal. A part of the alcohol is then distilled, the mixture filtered and the phenolphthalein separated from the filtrate by the addition of water.

Phenolphthalein occurs as a crystalline or amorphous powder, white or grayish white, melting at 250 to 253° C. (482 to 487.4° F.). It is soluble in 600 parts of water and in 10 of alcohol. Its solutions in acid liquids are colorless but turn red when the liquid is alkaline. The red color of the solution disappears if it is boiled with zinc dust, phenolphthalein (C₂₀H₁₄O₄) being formed.

Phenolphthalein heated on platinum foil should burn leaving no residue.

Actions and Uses—Phenolphthalein acts as a purgative but appears to possess no further physiologic action. A case of poisoning from taking 1 Gm. (15 grains) is reported.

Dosage—For adults the average dose is 0.1 to 0.2 Gm. (1.5 to 3 grains) given as powder in capsules, capsules or pills. It may be given with safety in doses of 0.5 Gm. (8 grains) and these doses seem to be necessary to secure its effects in bedridden patients or in obstinate cases.

SILVER LACTATE—Credé

A name applied to Silver Lactate, which see.

Manufactured by Fabrik von Heyden, Radebeul, near Dresden, Germany (Schering & Glatz, New York).

SPIROCHETES IN SO CALLED MOUSE CARCINOMA

The observation by Gaylord¹ and also by Calkins² that spirochetes occur in transplantable cancers in mice at once raises many interesting questions. Gaylord has demonstrated by means of Levaditi's silver method a characteristic spiral organism in the sections of ten consecutive spontaneous carcinomas of the breast in mice from Massachusetts, Ohio and New York. The same organism was found in transplanted tumors from all these sources.

In fresh material the organism is not readily demonstrable, but when found it is frequently motile. In the primary tumors the organisms are most numerous in the most actively growing parts where they occur in the stroma between the epithelial cells of the tumor and at the margins of the latter. In transplanted tumors they are found between the cells and in the connective tissue at the growing edge. The more malignant, i. e. rapidly growing, the tumor the greater the number of the organisms. Calkins proposes the name *Spirocheta microgyrata gaylordi* for this organism, which he regards as a variety of Lowenthal's *Spirocheta microgyrata*, described in 1906 in ulcerated human carcinoma, in a dog tumor, and in feces. Calkins, in New York City, has found the same spirochete as Gaylord in a spontaneous mouse tumor. It may be recalled that Borrel³ in 1905 observed spirochetes in mouse tumors, to which, however, he does not appear to have given any further attention. Other similar observations have been recorded also.

Gaylord makes this remark: "Our observations do not as yet establish an etiologic relationship between this organism and cancer of the breast in mice, but the presence of the organism in primary mouse cancer, with which it is regularly transplanted through many generations greatly increasing in number as the tumors increase in virulence, instead of interfering with, and finally preventing, transplantation as do bacteria, is suggestive." This certainly is a conservative conclusion, much further work by many investigators in different places is necessary to settle the question of the relation of this spirochete to mouse cancer, and it is quite safe to predict that a large part of the experimental cancer

investigation in the immediate future will be given to the solution of this question. We may expect, in the near future, to see a flood of literature on this phase of cancer.

The possibility that mouse cancer may be a spirochetal infection throws new light on many phenomena observed in the course of the enormous work in the transplantation of these growths. Heretofore, the results being viewed from the standpoint of the malignant tumors in man, such things as spontaneous healing, natural and acquired resistance and similar conditions have appeared explainable only by more or less far-fetched hypotheses. But if looked at from the microbic point of view, these phenomena become readily explainable in the more familiar terms: resistance, susceptibility, healing, and immunity in infections.

Naturally the results of future work on mouse tumors will be awaited with the keenest interest. It is not wise to apply purely anticipatory investigative results to human cancer. This much may be said, however. If mouse cancer, so-called, be shown to be of spirochetal origin, that would not necessarily mean that human malignant tumors are also spirochetal growths. The demonstration that growths in animals corresponding in certain essential points to human cancer are of infectious origin naturally would give strong support to the so-called parasite theory of cancer. Nevertheless the one fact (to mention only one) that the cancerous growths have been found without exception to be transplantable only within the species in which they arise spontaneously indicates that the causative agent, whatever its nature, in each case is peculiar to the species in question.

THE PHYSIOLOGIC ACTION OF ALCOHOL

The social and hygienic evils connected with the abuse of alcohol as well as its application in therapeutics, render important any new facts concerning the effects of this agent on the processes of metabolism. While in moderation it may be indulged in for long periods without apparent impairment of the general health, its excessive use is undoubtedly attended with functional and organic changes of a pathologic character.

It was long held that alcohol in moderate doses acted as a specific in "conserving the tissues," or, in other words, it checked metabolic waste. With the knowledge that it is oxidized in the body, it was recognized as a source of energy, and the view became generally accepted that it acts to some extent also as a food, thus sparing to a certain degree the proteid constituents of the body itself.

There appears, however, to be a diversity of opinion regarding its influence on the oxidation processes when taken in small repeated doses, and its exact value as a food is now questioned. Although much study has been devoted to a solution of the problem, the results have hitherto been meager.

1 Jour. of Infect. Dis. 1907 iv 155

2 Ibid. 171

3 Compt. rend. de la Soc. de Biol. 1905 LVIII 770

The Hygienic Laboratory¹ of the Public Health and Marine-Hospital Service has just issued an interesting and valuable report of studies on experimental alcoholism conducted by Dr. Reid Hunt, chief of the Division of Pharmacology of that institution. Experimental evidence is presented showing that extremely moderate amounts of alcohol when administered even for a short period may produce profound changes in metabolism, which, under certain circumstances, are deleterious in character.

Hunt's first series of experiments were made with animals that had been fed on oats soaked in alcohol. After a variable time these animals were given doses of acetonitrile, a substance which may be considered chemically as hydrocyanic acid in which the hydrogen atom has been replaced by the methyl group. This agent owes its physiologic activity to the liberation of hydrocyanic acid, and if this liberation is hastened its poisonous effects evidently become more manifest.

It was found that a hypersusceptibility to this poison had developed in the alcohol animals, as they succumbed to doses very much smaller than necessary to produce death in controls. This susceptibility was undoubtedly due to the continued ingestion of alcohol, as in all other respects the conditions of the animals were identical.

As alcohol is easily oxidizable in the body, it seemed reasonable to suppose that its continued use would increase the oxidizing power of the body—in other words, that tolerance is thus established.

These experiments show that this really does occur and that its continued administration also increases the power of the body to break up other alcohol groups, the methyl group of the acetonitrile being oxidized more readily in alcohol animals with a resulting increased liberation of hydrocyanic acid.

A second series of experiments is given showing that guinea-pigs fed on alcohol when given acetonitrile excrete more sulphocyanate, the formation of which from acetonitrile seems to be a protective reaction on the part of the body against this poison. This increased excretion is taken as further evidence that, under the conditions maintained in these experiments, there is a corresponding increase in the liberation of hydrocyanic acid.

It thus appears to be clearly proved that marked changes in the processes of metabolism are brought about by the administration of alcohol in doses small enough never to have caused symptoms of intoxication and that these changes are probably due to modification of the oxidation processes in the body.

Such changes do not follow the administration of the carbohydrates. On the contrary, Hunt shows that mice fed on oats soaked in dextrose acquire a distinct resistance to acetonitrile, and he therefore points out that too much importance should not be attached to the pretended sparing power of alcohol in practical dietaries.

These views are in accord with those of Chittenden,²

who, while he admits that alcohol in moderate doses may act as a food in the sense that it is a source of energy, denies that it is comparable with the carbohydrates, as, unlike the latter, it produces an increased excretion of uric acid, which is inimical to health.

Hunt has also shown in this report that the continued administration of alcohol markedly increases the excretion of ethereal sulphates in the urine. These latter products in all probability may be attributed to intestinal putrefaction—a condition often found in alcoholics.

The excretion of neutral sulphates was, if anything, decreased. The increased excretion of this product has been taken as a diminution of physiologic oxidation. These results, therefore, are an additional argument that alcohol has but a limited power of inhibiting oxidations.

While it is shown that the use of alcohol increases the power of the body to break up acetonitrile, modifications of the physiologic processes may not have the same deleterious effect in the case of other poisons. Alcohol is known to be a stimulant, a source of energy and heat, and the changes in physiologic functions observed by Hunt may eventually be shown to be of advantage in certain diseases.

THE EUROPEAN WAY

Von Bergmann died the other day—but not before he was able to feel the esteem in which his fellow-countrymen both professional and lay, held him. When recently he had attained to three score and ten his birthday was made the occasion of a national expression of very real affection. Truly, apart from his labors as scientist and surgeon, he had done the state some service. In appreciation some forty delegations called on him bringing gifts of every kind, and they consumed over five hours in passing before him. The universities were impressively represented. He had been very zealous during three wars and had served his government in other capacities, wherefore the Ministers of War and of Education were present to make acknowledgement of these debts. Men notable in the arts, in music and the drama paid tribute to his profound sympathies and culture, such as are characteristic of the highest type of German scholarship. Four important works were published in commemoration of this great birthday. He was probably most touched by the fact that at a banquet held on the invitation of the Berlin Medical Society, and attended by over 500 distinguished people, his wife and daughters being present, were toasted in recognition of what they (*das Frau Weibliche*) had done for him and through him for humanity.

A Parisian newspaper recently propounded the question: Who are the ten greatest Frenchmen of the Nineteenth Century? Fifteen million votes were received by Pasteur heading the pool with 7,300, a vote—a majority of 100,000 over V.

¹ Hygienic Laboratory Bulletin No. 73, Public Health and Marine-Hospital Service.
² Med. News, vol. lxxxvi, 721.

among these ten were also Curie and Roux, the great Napoleon was fourth. Evidently, then, science holds a high place in the esteem of the French people, they seem, over there, to be really grateful to the man eager to relieve suffering and to prolong life.

Berthelot, chemist and statesman, died recently in Paris under affecting circumstances. Coming home he found that his venerable wife had died suddenly, he went into his study and, evidently overwhelmed by the shock, presently himself expired. The noble pair were laid in state in the Panthéon in the presence of a great assemblage, including President Fallières, the cabinet ministers, the diplomatic corps, members of the French Academy, judges, deputies, senators and deputations from the learned societies. M. Briant, Minister of Education, took part in the imposing ceremonies, relating in an impressive speech the dead senator's achievements in chemistry and other sciences. When the orations were concluded all the troops composing the garrison of Paris defiled before the catafalque, and on that day every school in France was closed.

Here were three tributes to three great men of science. What was said of Berthelot was said also of Pasteur, and applies equally well to von Bergmann. "The man in him transcended the scientist and made him as beloved as he was eminent."

The point is that these great men were and are in memory affectionately appreciated by their countrymen. This is evidently the European way—which does not seem to be the American way. Possibly we have not yet evolved to that degree of civilization. By way of contrast we might note that among us, as in Paris, the question has been propounded: Who are the ten greatest living Americans—statesman, soldier, sociologist, preacher, author, railroad expert, athlete, educator, law-maker and conversationalist? Who these ten are we are not informed, we observe, however, with mortification, that no curiosity has been manifested concerning the greatest American physician. Even the greatest American scientist has been left most dismally out in the cold.

THE DIGESTIVE ACTION OF LEUCOCYTES

The important rôle played by leucocytes in removing and dissolving dead tissues, pneumonic exudates, foreign bodies, etc., depends on the powerful digestive enzymes which they contain, and which are liberated from the bodies of the leucocytes on their disintegration. Although all cells seem to be equipped with similar proteid-digesting enzymes, yet in the fixed tissues these seem to be relatively feeble, for under most pathologic conditions absorption goes on very slowly or not at all unless leucocytes are present, and the rate of digestion or absorption varies directly with the number of leucocytes. To illustrate: A tuberculous lesion may contain large areas of necrotic tissue which persist for a long time, but if some chemotactic substance is injected into these areas (e. g. iodoform

emulsion), the invading leucocytes promptly digest the dead tissue and remove it. It may be added, parenthetically, that many instances of supposed suppuration following such injections into tuberculous areas do not depend on pus infection, but on this liquefactive action of the leucocytes. As absorption of dead tissues and exudates is such an important process in medicine and pathology, recent studies into the nature of the enzymes of the leucocytes possess more than theoretical interest.

The chief studies on this subject have been made by E. L. Opie¹ in the Rockefeller Institute, and have yielded many interesting results. In the first place, it has been demonstrated that the chief proteid-splitting enzyme of the polynuclear leucocytes is quite different from the proteid-splitting enzymes of nearly all the other cells of the body, for the enzymes of the polynuclear leucocytes act best in a faintly alkaline medium, whereas the ordinary cellular enzymes act best in an acid medium, and little or not at all in alkaline fluids. The mononuclear leucocytes and the lymphatic tissues from which they come seem to contain chiefly enzymes which, pepsin like, require an acid medium. Apparently the only fixed tissue which contains enzymes acting best in alkaline media is the bone marrow, this chemical observation supports the microscopic evidence that the polynuclear leucocytes arise in the bone marrow, while the mononuclears come from the spleen and lymph glands. The fact that the proteid-digesting enzymes of our fixed tissues require an acid medium for their action, would suggest that the failure of living tissues to digest themselves depends on the "alkalinity" of the blood, and it is possible that this explanation is of some importance. But that being so, the question arises: What holds the leucocytic enzymes in check if they are best adapted to an alkaline medium? The apparent answer to this seems to lie in the observation that in the normal blood plasma there is contained a substance which has the power of holding the leucocytic enzymes in check. This "anti-enzyme" is present in but limited amounts, it would seem, and hence when large numbers of leucocytes accumulate and disintegrate they may over-saturate the amount of anti-enzyme present and digest any dead proteids that may be at hand. It is also quite possible that in infected or necrotic areas substances form which neutralize or destroy the anti-enzymes, and thus permit the leucocytes to begin their digestive action.

The antagonistic action of these two constituents of the blood affords an instance of the way in which vital processes are held within certain suitable limits by means of balancing one action against another. As an instance illustrating the effects of the balancing of leucocytic enzymes by the anti-enzymes of the serum in a special case, may be mentioned the conditions observed in the rabbit. It is well known by laboratory workers that infection with pus microbes in rabbits does not usually produce the creamy pus seen in human infections, but

¹ Literature will be found in the Jour. Exp. Med. 1907, ix, 207.

rather a solid cheesy mass of leucocytes and dead tissues is formed. This is explained by the fact that rabbits' leucocytes contain but a feeble proteid-digesting enzyme, while rabbits' blood serum is rich in the anti-enzymes, hence digestive softening of the necrosed cells does not readily take place.

THE MEDICAL EXPERT

If any further data are necessary to convince the most conservative that changes are needed with regard to expert testimony in our courts, the proceedings in the recent Thaw trial will certainly furnish them. Here weeks of time were consumed by the clashing of the alienists and the wrangles over their testimony, yet nothing could have been more futile or inconsequential than that testimony.

A juryman has graphically recorded his impressions and in terms singularly just. In examining one expert the attorney for the people displayed "an amazing grasp of an intricately technical subject." The prosecutor is not, of course, a medical man, yet his knowledge of a matter essentially medical was manifestly much greater than that of the unhappy witness, and the proceedings were strongly suggestive of "a cat playing with a mouse." Another alienist appeared, from the jury box, to be "one of those rare souls who are unconscious of time, since they inhabit eternity, and as his incumbency of the stand dragged through session after session the humor of the situation began to appeal even to the impatient twelve. After various imposing and impressively qualified alienists had promptly answered 'rational' to a hypothetical question an hour and a quarter long, various other equally imposing alienists with equally impressive qualifications answered the same question quite as promptly with the word 'irrational.'" It seemed to this juryman time wasted to have placed these experts on the stand to give answers so foreordained, they might best have been stood up in line and cancelled in pairs so that by a sort of *reductio ad absurdum* it might be seen by the remainder which side to credit.

The chief point at issue in this case turned on the question of the defendant's sanity. Yet here the jury seemed to pay no attention whatever to the opinions of the experts, who about evened up, as the juryman put it. These laymen judged the matter of sanity quite for themselves, and on what they deemed common sense principles.

What physician will not be mortified by this editorial observation in the *New York Sun*: "Nor do we purpose to waste any time on the great mass of expert testimony for or against the prisoner. Suffice it to say that in this murder case, in which a liberal purse has been at command, alienists of more or less prominence were produced who testified that Thaw at the time of the killing was insane or did not know that the murder was wrong. On the other hand, many experts of equal or greater eminence produced by the District Attorney swore that Thaw was sane at the time."

The subject of medical expert testimony demands drastic revision. Were it not best that we undertake this revision among ourselves, lest, to our humiliation, the laity through legislative bodies take the matter quite out of our hands? There are many views expressed and many plans suggested. Those which should prevail must be based on the position that alienists should no longer be medical advocates for the side which retains them, they should no longer be aligned as partisans, with their respective legal counsel.

THE MOLOKAI LEPRO SETTLEMENT

The territory of Hawaii has the best organized and most extensive institution for dealing with leprosy in existence. Segregation was first attempted in 1866 in the establishment of the leper settlement on Molokai island. The administration, while at first disliked, has increased in popularity. Many lepers come voluntarily for examination, others receive from the board of health an invitation which is practically an order. All the patient's or suspect's expenses to and from the examining station at Honolulu are paid by the government. The board of examiners consists of five physicians, one of whom is bacteriologist to the board of health and another skilled microscopist known as assistant bacteriologist. Attempts at the curative treatment of leprosy have been many, and several imagined specifics have been tried at the settlement, but so far with uniformly unsuccessful results. Medical treatment is carried on by a resident physician and his assistant and is frequently of much benefit even though not curative. Surgical operations are performed more frequently than formerly and meet with considerable success. While some lepers or suspects have been granted the privilege of re-examination and of return to their homes, of late years they have preferred to remain on the island, where they are assured of a comfortable living and better social privileges than they could enjoy in their homes. The United States Leprosy Investigation Station is within the borders of the settlement, and it is hoped that its work will throw new light on this mysterious disease. The problem of the disposal of the children born on the island or left by leprous parents has been partly solved by a girls' home under the care of the Sisters of St. Francis and it is proposed to establish a similar home for boys, which may give the non-leprous children of leprous parents an industrial education fitting them for a useful life. It is proposed by L. E. Pinkham, president of the board of health, that dairy farming be taught these boys as a branch of agriculture needing development in the islands.

THE TRANSFORMATION OF DIABETES MELLITUS INTO DIABETES INSIPIDUS

The peculiarities of diabetes mellitus in elderly people are, some of them well known and usually recognized. The fact that the glycosuria may disappear under the influence of a complicating nephritis and may never return has long been known and is very characteristic of a certain type of case. The appearance of the sugar with the continu-

common, as Teschemacher¹ has pointed out. Although the polyuria does not always go hand in hand with the glycosuria, as, for example, in the so-called diabetes depiciens, yet this is the rule, and in most patients when the glycosuria diminishes the amount of urine likewise becomes less. Teschemacher cites several cases in which the glycosuria disappeared, even with the patient on a mixed diet, but the polyuria, with thirst and debility, persisted. The patient thus presented at this stage the picture of diabetes insipidus. Similar cases have been recorded before, and have been described as examples of a transition from one disease into the other. That this is a proper interpretation is doubtful, for, as in one remarkable case cited by Teschemacher, the sugar may reappear after a long period of years. So far as the clinical aspects of such cases are concerned they are finally diabetes insipidus. These patients must not be confounded with diabetics who develop chronic interstitial nephritis with polyuria, in whose urine there is so little albumin that it is readily overlooked.

USING THE FOOD AND DRUGS ACT TO MISLEAD

We have previously called attention to the use which some of the food and drug manufacturers and promoters are endeavoring to make of the guarantee clause of the national Food and Drugs Act. The matter has become of sufficient importance to attract the attention of the Secretary of Agriculture, who has issued a statement on the subject. He says: "A serial number and the statement that a food or drug is 'guaranteed under the Food and Drugs Act June 30, 1906,' does not mean that the United States Government guarantees the purity of the article or guarantees that it is what the label says it is. It simply means that the manufacturer guarantees it to be pure and free from adulteration and that he warrants every fact stated on the label to be true. The government assumes no responsibility for the guarantee. On the contrary, the serial number is assigned to fix the responsibility where it belongs—on the manufacturer—and to protect innocent dealers. Such advertising as 'after Jan. 1, 1907, the United States Government will protect you by an official serial number,' or statements that the food product is 'approved by the pure food commissioners,' must be stopped at once. If this outrageous misrepresentation does not cease the department will publish a list of the manufacturers who are indulging in this campaign of deception. Manufacturers who are deceiving the public about the guarantee will lie about the quality of their products. The pure food law is going to be administered fairly. Its primary purpose is to protect the consumer." It is to be hoped that this public announcement of the facts in the daily press will put a stop to the brazen and unjustifiable efforts on the part of a certain class of manufacturers to make capital out of the very means that have been devised for restricting them and for preventing them from deceiving their customers. Certain drug firms, for instance, have announced in large letters that they were among the first ten firms to file their guarantees intimating that there was some particular virtue in such a proceeding. These tactics are intended to deceive and do deceive, those who are not conversant with the provisions of the law.

Medical News

ALABAMA.

Quarantine Is On.—Nominally the quarantine season at Mobile began April 1. Dr. Edward Francis, who is in charge at Fort Morgan, will have personal charge of the entire quarantine plant.

Senn in Mobile.—At the annual meeting of the Medical Association of the State of Alabama, the Jerome Cochrane lecture was delivered April 17, by Dr. Nicholas Senn, Chicago, whose topic was "The Final Triumph of Scientific Medicine."

Society Meeting.—At the annual meeting of the Coosa County Medical Association, held April 2, Dr. William A. Holmway, Lauderdale, was elected president, Dr. Cecil K. Maxwell, Kellyton, vice president, and Dr. Eugene Argo, Goodwater, censor.

College Notes.—The trustees of the University of Alabama, at a session in Tuscaloosa, took over the Medical College of the University of Alabama, Mobile, and discussed plans for the improvement of the university. The commencement exercises of the Medical Department of the University of Alabama (Mobile Medical College) were held April 15, when a class of thirty was graduated. The dean of the faculty, Dr. Rhett Goode, delivered the address and the president, J. W. Abercrombie, of the University of Alabama, presented the diplomas to the graduates. Birmingham Medical College graduated a class of fourteen April 4. T. G. Bush delivered the address of the evening. Dr. Benjamin L. Wyman, dean of the college, presented the diplomas and Dr. R. M. Cunningham delivered the charge to the graduates.

ARIZONA.

To Safeguard Health in Territory.—Dr. James W. Coleman, Tucson, recently appointed superintendent of public health for the territory, has sent out letters to the different clerks of the county boards of supervisors, asking their cooperation in the concerted effort he is endeavoring to make against contagious diseases and their needless spread.

Society Meeting.—The Maricopa County Medical Society, at its annual meeting, held in Phoenix, April 6, elected the following officers: President, Dr. James M. Sweetnam, vice-president, Dr. John W. Foss, secretary-treasurer, Dr. Elmer C. Bond, delegate to the territorial association, Dr. Ancil Martin, alternate, Dr. John W. Foss, and censors, Dr. William I. Simpson, Otto E. Plath and John W. Thomas, all of Phoenix.

ARKANSAS

"Drummers" Fined.—Dr. James Anderson, Hot Springs, pleaded guilty on March 28 to violating the local anti-drumming ordinance. He was fined \$25 and his license revoked. Dr. W. W. Mercer, Hot Springs, on April 8, was fined \$100, and his license revoked on account of violation of the anti-drumming ordinance. He gave notice of appeal.

Society Meetings.—The Garland County Hot Springs Medical Association at its regular monthly meeting, April 2, elected the following officers: President, Dr. Oliver H. Burton, vice-presidents, Drs. Albert H. Tribble and Morgan F. Mount, secretary, Dr. Joseph S. Horner, treasurer, Dr. Randolph Brunson, delegates to the state association, Drs. Arthur U. Williams and Frank W. Jelks, and alternates, Drs. Oliver H. Burton and Eugene C. Hay, all of Hot Springs. At the annual meeting of the Howard County Medical Society, held in Nashville, Dr. Cadwalader W. Wright, Buck Range, was elected president, Dr. Evan M. Black, vice president, Dr. William H. Toland, Mineral Springs, secretary-treasurer, Dr. David A. Hutchinson, Nashville, delegate to the state society, and Dr. James M. Daly, Nashville, alternate. The physicians of Siloam Springs have organized what is to be known as the Physicians' Post Graduate Medical Club.

CALIFORNIA.

Hospital News.—Drs. Charles C. and Curtis O. Falk have opened temporary quarters for the Marine View Hospital in the old Murray Hospital, Eureka. The Bird Haven Home for the Feeble Minded and Incompetent has been incorporated at San Jose with a capital stock of \$75,000. The new Southern Pacific Hospital, San Francisco, is to be constructed of reinforced concrete and will have accommodation for 200 patients.

COLORADO

Society Election.—The Woman's Medical Society of Denver at its annual election April 5, elected Dr. Laura L. Tiehardt president, and Dr. Mary Hawes, vice president. Dr. Eleanor M.

Lawney, the retiring president, gave an address on "Causes of Death."

State Board Officers.—The State Board of Health at its first meeting April 8, organized for the biennium. Dr William H. Davis, Denver, was elected president, Dr Minnie C T Love, Denver, vice-president, Dr Hugh L Taylor, Denver, secretary, and Dr Frank N Carrier, Canon City, treasurer.

Reappointments.—Dr Matt R Root, Denver, has been reappointed surgeon general of the Colorado National Guard, and Dr Samuel B Scholz, Denver, inspector general.—Drs Seymour D Van Meter, Carey K Fleming, and T Willis Miles, all of Denver, have been reappointed members of the Seattle Board of Medical Examiners.

CONNECTICUT

Sanitarium Burned.—The Grand View Sanitarium, South Windham, was destroyed by fire early on the morning of April 6. There were 16 patients in the institution at the time, one of whom was burned to death.

Gifts to Medical School and Hospital.—By the will of the late Gen Samuel E Merwin, New Haven, \$5,000 is devised to Yale University for the use of the medical school and \$25,000 is bequeathed to the New Haven Hospital.

Elections.—At the monthly meeting of the Celtic Medical Society of Waterbury, held March 25, Dr Bernard A O'Hara was elected president, vice Dr Edward W McDonald, deceased, and Dr Thomas J Kilmartin, vice president, to fill vacancy.—At the annual meeting of the New London County Medical Society, held in Norwich, April 4, the following officers were elected: President, Dr Harry M Lee, New London, vice president, Dr Morton E Fox, Uncasville, clerk, Dr Edwin C Chipman, New London, delegates to the state society, Drs George R Harris, Norwich, and Carlisle F Ferrin, New London, counselor, Dr Edward P Brewer, Norwich, county reporter, Dr Patrick J Cassidy, Norwich and censors, Drs Charles E Bravton Stennington, William Witter, Norwich, and Lewis S Paddock, Norwich.

GEORGIA

Personal.—Dr Francis M Ridley, La Grange, has been appointed surgeon of the La Grange Division of the Atlanta, Birmingham & Atlantic Railway.—Dr William C Pumpelly, Macon, has been seriously ill with pneumonia.—Drs James B Baird and William S Elkin have resigned from the medical staff of Grady Hospital, Atlanta.

Hospital Notes.—It is reported that the officers and employees of the Southern Railway will build in Atlanta a hospital to cost \$200,000, for the treatment of railway men and their families, as a memorial to the late Samuel Spencer, president of the road.—St Mary's Hospital has been established in Athens by Drs Henry M Fulklove and J Peebles Proctor.

Children and Teachers to be Examined.—At a recent meeting of the ordinance committee of the City Council of Atlanta it was decided to report an ordinance requiring the medical examination of all pupils and teachers of the public schools once a year, the examination to be made by a ward physician except where a parent or guardian prefers the services of the family physician.

IDAHO

Personal.—Dr Hugh V Scallon has been elected mayor of Coeur d'Alene.—Dr Hugh France, Wardner, has been appointed physician of Shoshone County.

Epidemic Diseases.—The public school of Genesee has been closed on account of the prevalence of mumps, measles and chickenpox.—A number of cases of smallpox discovered in Wallace has caused the suspension of all public meetings in the city until further notice.

Society Meeting.—At the annual meeting of the South Idaho District Medical Society, held in Boise, April 4, the questions of prophylaxis of tuberculosis and insurance examination fees were discussed. The following officers were elected: President, Dr Jesse C Woodward Pavette, vice president, Dr Adolph Blitz, Boise, secretary-treasurer, Dr John M Taylor, Boise, members of the executive committee, Drs James A Young, Caldwell and William B Lyman, Boise. The society endorsed the candidature of Dr Edward E Maxey, Boise, for secretary of the State Board of Health and of Dr Orville I Allen, Bellevue, as a member of the State Board of Medical Examiners.

ILLINOIS

Personal.—Dr William R Parkes has been reappointed health commissioner of Evanston.—Dr Wilfred H Gardner, Bloomington, has gone to Germany.

Intern Examination.—An examination was held April 11 at Cook County Hospital, for internships at the Cook County Institutions, Dunning. The board was composed of Drs William L Brum, O C Willhite, Charles E Kahike, John D Robertson and J B Caldwell.

Hospital Notes.—Riverview Hospital, Kankakee was opened to receive patients March 25. Dr James Dougherty, Chicago, is house physician of the institution and the attending staff is made up of Kankakee County practitioners.—The Oak Park Hospital was formally opened by Bishop Muldoon April 4. Dr John W Tope representing the hospital staff.

Legislative Notes.—The osteopathic bills (house 318 and 319), are on the order of second reading in the House of Representatives. No hearing seems to have been given on these bills in the committee. The osteopaths behind these bills are making a determined effort to force their passage but the legislative committee of the Illinois State Medical Society and the Illinois State Board of Health are making an equally determined effort to see that they shall not pass.—The anti vivisection bill (senate 267) is now on first reading in the House of Representatives.—The optometry bill (now house bill 845) is on second reading in the house.—The medicine peddlers' bill (senate 341 and house 474) are still in the house—committee on license of the house, in which it is believed they will remain.

Chicago

New Health Commissioner.—A committee of physicians requested by the mayor to select a candidate for health commissioner, at an adjourned meeting, April 13 fixed on Dr William A Evans for that position. Mayor Busse has appointed him to the office.

Howard Kelly in Chicago.—The Nicholas Senn Club had as its guest of honor, April 15, Dr Howard A Kelly of Johns Hopkins University, Baltimore who read a paper on "The Recent Advance Work on Genitourinary Affections." Among the speakers were Drs Henry T Byford, Emil Reis and Frank Lin H Martin. Dr Lucy Waite acted as toastmaster.

Memorial Hospital.—The Council of the Chicago Medical Society, at a meeting, April 9, unanimously endorsed the establishment of an emergency hospital in the central portion of the city, to be known as the Iroquois Memorial Hospital. The hospital is to be, save in name, a branch of the Cook County Hospital and in return for the use of its name, the Iroquois Memorial Association has agreed to contribute the \$2,000 already collected and such other sums as may be raised by members of the association.

Personal.—Dr Joseph B DeLee has gone to Europe for a four months trip.—Dr Clarence L. Whetton delivered the public address on tuberculosis, April 15, at Shelbyville under the auspices of the Shelby County (Ind.) Medical Society.—Dr Gustavus A Fischer was robbed of his watch and \$6 in money April 10.—Dr Horatio S Brewer was seriously injured by a collision with a street car April 10, while pursuing pickpockets who had robbed him.—Dr Charles S Bacon returned April 13 after a two months' trip abroad.

Mortality Still High.—During the week ended April 13, 717 deaths were reported, equivalent to an annual death rate of 17.74 per 1,000. Of the 31 deaths in excess of those reported during the previous week, 12 of the decedents were under one year of age and 15 over 60 years of age. The death rate represented an increase of 4.5 per cent over the preceding week and of 15.04 over the corresponding week of 1906. Pneumonia caused 132 deaths, consumption, 73, heart disease 60, violence including suicide and nephritis each 51, acute intestinal disease 41 and cancer 36. Of the communicable diseases, scarlet fever caused 9 deaths, measles and diphtheria each 8, whooping cough, 6, typhoid fever 5 and influenza.

INDIANA

Communicable Diseases.—The postmaster at LaVelle is ill with smallpox and the postoffice is under quarantine.—On account of the prevalence of scarlet fever the grade school in Peterburg have been ordered closed.

Personal.—Dr W. J. Bluffton March 28 to June 10.
Arctic.—Dr J. Bluffton created on last w.

Physicians' Building—An office building, five stories high, is to be erected, at a cost of \$100,000, at Meridian and New York Streets, Indianapolis. The building is to be used exclusively for offices for physicians and dentists.

Library Association Formed—At a recent meeting of the Fort Wayne Medical Society, the Fort Wayne Medical Library Association was formed, with Dr George W McCaskey as president, Dr Benjamin P Weaver, secretary, and Dr Alfred L S Kane, treasurer.

IOWA

Local Society Organized—At a meeting of the physicians of Fort Madison, March 20, a local medical society was organized, with Dr Frank C Roberts, president, and Dr William C Kasten, secretary.

Personal—Dr Charles Palen has been re-elected city physician of Dubuque—Dr Joseph M Emmert, Atlantic, has been nominated by the governor as a member of the Board of Pardons and Parole—Dr Frederick Albert has been appointed city physician of Mason City, vice Dr Channing E Dakin.

Tuberculosis Bills—The bill appropriating \$50,000 for the completion of the main building for the hospital for consumptives at Sanitarium, near Iowa City, has been passed by the legislature. The bill includes an annual appropriation of \$5,000 for the dissemination of literature on tuberculosis.

MARYLAND

Banquet of the University Alumni—The first banquet of the General Alumni Association of the University of Maryland was held in Baltimore, April 10. Among the medical speakers was Dr E Miller Reed. The proposition for a University Club met with much favor, and a committee of 100 was appointed to raise an endowment fund.

Hospital for Colored Patients—The Union Hospital Association, an association of colored people of Frederick, has purchased and equipped, at a cost of \$30,000, a building soon to be opened as a hospital. The house has eight rooms, two of which will be used as public and four as private wards. The operating room is supplied with the equipment of the Emergency Hospital, which has ceased to exist. Dr William G Bourne, Frederick, is house physician.

Baltimore.

Fulton Resigns—Dr John S Fulton, for ten years secretary of the State Board of Health, has resigned to become secretary of the International Conference on Tuberculosis. He will make his headquarters at Washington, D C.

Hospital Report—The report of St Joseph's Hospital for 1906 showed that during the year 2,525 patients were admitted, all but \$98 of which were free patients. The percentage of deaths was 4.75. In the dispensary 9,811 patients were treated and 10,050 prescriptions were filled.

State Society Meeting—The one hundred and ninth annual meeting of the Medical and Surgical Faculty of Maryland will be held in Baltimore, April 23 to 25. The subject of the address of the president, Dr Hiram W Woods, will be "The Medical and Surgical Faculty Its Debts to Itself and the Public." The annual oration will be delivered by Dr George H Simmons, Chicago, on "The Campaign Against the Domination of Therapeutics by Commercialism." A special meeting is to be held after the oration, the object of which is to set before the members the need of a new faculty home and the means of obtaining it. The subject will be presented by Dr Edward N Brush, chairman of the building committee, and Dr Robert W Johnson, chairman of the council. At the afternoon session, April 25, there will be a joint meeting of the Maryland State Conference of Charities and the Maryland State Conference of Women's Clubs. At this session the social evil will be discussed by Dr Prince A Morrow, New York, whose subject will be "The Prophylaxis of Social Diseases." Dr Lillian Welsh will speak on the "Prophylaxis of Social Disease in the Home," and Dr Charles B Emerson, who will take up the "Duty of the Organized Medical Profession in Fighting the Social Evil." The annual banquet will be held in Faculty Hall on the evening of April 25.

MASSACHUSETTS

Supreme Court Sustains Verdict—The Supreme Court of Massachusetts has sustained the verdict of \$1,700 obtained by Dr John Fitzhugh Amesbury against the Boston & Maine Railroad for injuries received by the plaintiff at a railroad crossing in Amesbury.

Hospital Wing Opened—The new surgical wing of the New England Deaconess' Hospital, Longwood, Boston, was opened with appropriate ceremonies April 8. The new building has a capacity for 44 patients and is furnished with a double suite of operating rooms. The property as it now stands has cost \$150,000, and \$30,000 additional is necessary to cover the cost of the completed and equipped building.

Gifts to Hospitals—By the will of the late Jabez K Montgomery, \$5,000 is bequeathed to the Rufus S Frost General Hospital, Chelsea—The late Eliza D Dodge, Worcester, in her will gave \$5,000 to the Worcester Memorial Hospital and \$1,000 to the Baldwin Hospital Cottages—By the will of the late Mrs Eliza Orne Ropes, \$5,000 is bequeathed to the Salem Hospital.

Medical Men Organize—The Boston Society of Examining Physicians and Surgeons was organized April 3, at a meeting of a number of physicians connected with different semi-public corporations and life insurance companies. The following officers were elected: President, Dr Francis D Donoghue, vice presidents, Drs Frank E Allard and Edward M Greene, secretary, Dr Charles T Cutting, and treasurer, Dr Charles O Kepler.

Smallpox—At Lawrence seven additional cases of smallpox have been developed, making a total of 38—The 15 immigrants who were detained on the arrival of the steamship *Oymrie*, on account of smallpox, have been released from the detention hospital—Seven new cases of smallpox have been discovered in Chelsea, and the isolation hospital now contains eight patients. All the cases are said to be directly traceable to the epidemic at Lawrence.

Personal—Dr S Alphons Daudelin, Worcester, has been selected as United States commissioner at the International Maritime Exposition, Bordeaux, France—Dr John J Bartley, Lawrence, has been appointed city physician, vice Dr Timothy J Daly—Dr Roy V Baketel has been appointed school physician for Methuen—Dr J William Spooner, Hingham, has been reappointed medical inspector for Plymouth County—Dr Joseph R Charron has been made chairman of the board of health of Turners Falls.

MICHIGAN

President Buhl Dies—Theodore D Buhl, president of Parke, Davis & Co, Detroit, died April 7.

Personal—Dr Walter H Sawyer, Hillsdale, is reported to be in a serious condition from septicemia, due to an operation wound—Dr George E Reyecraft has been elected mayor of Petoskey—Dr William W Lathrop, formerly in charge of the Jackson Sanitarium, had a narrow escape from death when his clothing became entangled in the shafting of the engine room of the institution, April 3—Dr Malcolm E Smith, Grand Rapids, has started for Katalla, Alaska, where he will be house surgeon in the new Pierpont Morgan Hospital—Dr Robert B Armstrong has been elected mayor of Charlevoix.

Hospital Notes—Dr Ernest M Vardon has sold his hospital at Hillsdale to Dr Arthur G Doty, and will move to Albion—The Kalamazoo Hospital Association has raised already more than \$11,000 of the \$25,000 needed to wipe out the debt of the institution—At a citizens' meeting of Calumet the disposal of the Ernest Bollman cash donation of \$20,000 and four lots for a hospital location was considered. It is the intention of the committee to raise a like sum, that a hospital large enough for the needs of the community may be erected—The State Sanatorium for Tuberculosis, Howell, was ready to receive patients April 1. It was then able to accommodate 100 patients.

MISSOURI

Banquet to Medical Members of General Assembly—The program for the banquet to the medical members of the forty-fourth General Assembly of Missouri by the St Louis Medical Society and the Medical Society of City Hospital Alumni in recognition of the good work accomplished in state legislation, has been arranged for April 26 at 8 p m, at the Planters' Hotel. Tickets may be had of any member of the committee and from the officers of the societies. Dr George Homan is chairman of the committee, Dr Adolph G Schlosser treasurer, Dr Stewart, secretary. Dr William G Moore will officiate as toastmaster. It is expected that the governor, the president of the senate, the speaker of the house, ten or more members of the senate and house, the presidents of all the state medical societies and the president of the State Board of Health will be guests of honor on this occasion.

Hodgen Memorial Meeting—Arrangements for the memorial meeting in St. Louis in honor of the twenty fifth anniversary of the death of Dr. John T. Hodgen, a former president of the American Medical Association, to be held in the Y. M. C. A. Hall, April 28, are being rapidly perfected. Dr. Warren B. Outten will preside as chairman of the committee of arrangements. The exercises will begin at 3 p. m., and will be as follows:

Invocation Rev. Samuel J. Nicolls
Address Dr. Hodgen as a National and International Figure in Medicine Joseph M. Mathews, M.D., Louisville, Ky.
Address His Educational Influence in the Mississippi Valley Edward W. W. Schaeffler, M.D., Kansas City, Mo.
Address The Debt of Missouri to His Example and Memory Charles H. Wallace, M.D., St. Joseph, Mo., president Missouri State Medical Association.
Address His Power and Influence as a Teacher Over His Classes Henry C. Fairbrother, M.D., East St. Louis, Ill.
Address His Worth as a Citizen Charles Nagel, Esq., of the St. Louis Bar.
Address His Executive and Administrative Abilities in Public and Private Stations Le Grand Atwood, M.D., Ferguson, Mo.

NEW MEXICO

Railway Hospital to be Built—It is reported that the El Paso & Southwestern Railroad Company will build a large hospital for the use of its employees at Alamogordo.

Insane Asylum Bonds Authorized—The trustees of the New Mexico Insane Asylum, Las Vegas, have been authorized to issue bonds to the amount of \$105,000 for needed improvements.

To Report Contagious Diseases—At the March meeting of the Donna Ana County Medical Society a motion was adopted that the society strongly advise parents and good citizens immediately to report to their family physician or the health officer any or all cases of diseases of whatsoever nature, that they may be investigated and proper precautions taken.

Infirmiry for Silver City—Mr. Frank G. Thomson has presented the New Mexico Cottage Sanatorium for the Treatment of Tuberculosis with the necessary funds for the building of an infirmary. This building will complete the original scheme for the institution with the exception of a research laboratory. There are now 50 buildings of durable cement construction. Almost all of the funds needed have been presented to the institution.

NEW YORK.

State Charity Board Officers—The State Board of Charities, at its annual meeting, elected William Rhinelander Stewart president and Stephen Smith vice president, both of New York City.

Senate Passes Bills—The senate has passed the medical union bill which provides for one state board of medical examiners instead of three, as at present, and the Armstrong bill making an appropriation of \$1,000 for a commission to select a site for a new state hospital for the insane.

Mary Putnam Jacoby Fellowship—The Woman's Medical Association of New York has raised \$25,000 to be used for a fellowship to bear the name of Dr. Mary Putnam Jacoby. The income of the fund will be used to pay the expenses of a woman medical student who wishes to study abroad.

Physicians' Club Organized—At a meeting of the physicians of Newark, April 4, organization was effected and the following officers were elected: President, Dr. Augustus A. Young, vice president, Dr. Jared A. Reed, secretary, Dr. William H. Jessup, and treasurer, Dr. Edward P. Thatcher.

Personal—Dr. John C. Otis has been appointed commissioner of public works at Poughkeepsie.—Dr. John L. Heffron has been appointed acting dean of the Syracuse University, Medical Department, during the absence of the dean, Dr. Gaylord P. Clark, who has gone to Europe.—Dr. William D. Peckham has been appointed health officer of Utica.

To Limit Expert Testimony—Assemblyman Moreland has introduced a bill to limit expert testimony of alienists in all murder trials where insanity is pleaded as a defense. The bill also prevents hypothetical questions being asked in any criminal case where insanity is a defense. The idea is to do away with experts who receive enormous fees and seem prone to testify as the side which retains them wishes.

Medical Legislation—Governor Hughes has signed the following bills: The Rogers bill making appropriations for state hospitals by which Binghamton Hospital gets \$50,000 for a new dining room and kitchen, \$81,000 for a nurses' home and \$7,500 for water supply; Middletown Hospital gets \$81,000 for a nurses' home; Hudson River Hospital \$81,000 for a nurses' home, and Kings Park Hospital, \$62,000 for a

new laundry.—Mr. Boshart's, providing that prosecutions for penalties for violations of the agricultural law may be brought in the county where the product is exposed for sale or in the county in which the adulteration or violation occurred.—Mr. Prentice's, incorporating the society known as the Russell Sage Foundation for the purpose of maintaining a fund and applying the income to the improvement of social and living conditions in the United States.—Mr. Wainwright's authorizing Port Chester to raise a tax of not more than one tenth of 1 per cent for public health purposes.

New York City

Personal—Dr. Monta Wainfort Jamison, Middleton, has returned after an extensive tour of Europe.—Dr. Charles E. McBurney has been spending the winter in California for his health.

Competition for Hospital Positions—Four salaried positions on the resident staff of the Seton Hospital, Spuyten Duyvil, New York City, are open for competitive examination, April 29. Application should be made to Dr. Lewis F. Frissell, 113 East Fifty-sixth Street, New York City.

Contagious Diseases—There were reported to the sanitary bureau for the week ending April 6, 415 cases of measles, with 21 deaths, 302 cases of scarlet fever, with 16 deaths, 386 cases of tuberculosis, with 211 deaths, 319 cases of diphtheria, with 38 deaths, 92 cases of typhoid fever, with 18 deaths, 74 cases of whooping cough, with 12 deaths, 18 cases of cerebrospinal meningitis, with 10 deaths, 73 cases of varicella and 4 of small pox, making in all 1,773 cases, with 326 deaths.

Society Election—At a meeting of the Brooklyn Medical Society the following officers were elected: President, Dr. Hugh E. Rogers, vice president, Dr. William H. Rankin, recording secretary, Dr. Alfred E. Shipley, corresponding secretary, Dr. Edward W. Wright, treasurer, Dr. Edwin A. Hatch, librarian, Dr. Lewis E. Meeker and trustees, Drs. Algernon T. Bristow, Alfred Bell, James W. Ingalls, William B. Brader, John H. Droge, James C. Kennedy, John D. Sullivan, Elias H. Bartley and Richard W. Westbrook.

Opposition to Free Eyeglasses—A number of protests against supplying free eyeglasses to school children with defective vision were made at the last meeting of the Board of Education. The Association for Improving the Condition of the Poor believes that to supply eyeglasses would be both demoralizing and pauperizing, and would fail to remove the cause of defective vision. Similar protests were also entered by the City Club, the Brooklyn Bureau of Charities, the Children's Aid Society, the Brooklyn Children's Aid Society, and several other organizations.

Medical Instruction for East Side—The American Life Saving Society has just established a medical bureau under the direction of Dr. G. Fish Clark. The aim of the bureau will be to instruct parents in the crowded districts of the city how to protect themselves and their children from disease. Advice and instruction on first aid to the injured, sanitation and hygiene will be given without charge to all who will come to the bureau in the afternoon between 5 and 6 o'clock. Five lectures on these subjects will also be given at the city baths by Dr. Clark and Superintendent Brennan.

The Typhoid Scare—It has practically been determined that the typhoid outbreak at Katonah was due to contamination of the village water supply by Italians employed at Cross River Dam. No new cases have been reported but it seems that there have been thirteen cases in all.—The increase in the number of typhoid cases in Manhattan has been so sharp since the middle of March that the county medical society has called the attention of its members to the fact. For the week ended March 30 there were 106 cases with 12 deaths in Manhattan, and for the first week in April there were 18 deaths as compared with 6 deaths from this disease for the corresponding week of last year. The boiling of all water used for drinking purposes has been advised.

The Milk Question—The committee of public health of the Board of Aldermen which has been holding public hearings on the milk question decided at a special meeting April 11 in favor of the ordinance which if passed will require that the milk from every dairy supplying New York shall be tested by the Health Department once a month and that any milk showing over 500,000 bacteria to the cubic centimeter will have to be pasteurized before being sold. There are many other points to the measure, but it is said that it will not be signed by the mayor until he has heard from the special commission which is investigating the matter. This commission has not yet reported but it is said that it will still be invoked. The state is supposed to

cattle and to pay the owners a certain part of their value, but the appropriation has not been large enough to carry out this provision of the law. A bill is being prepared for presentation to the legislature sometime during the coming week requiring the reporting of illness among employes in dairies, and sickness among cows. If employes are found to be ill they must be segregated. If cows are ill they are to be killed and the owners will receive compensation for them. The bill also provides an appropriation for recompense to cover the latter part.

Centennial of the New York College of Physicians and Surgeons.—The College of Physicians and Surgeons of New York is just passing its one hundredth anniversary. The charter bears the date of March 12, 1807. The first class graduated in 1811, this year also being notable for the induction into office as president of Dr. Samuel Bard, who had been the physician of George Washington and a former dean of the medical faculty of Columbia College. Two years later, 1813, this school absorbed the entire medical faculty of Columbia College, thereby increasing the strength and prestige of the teaching body. General medical and surgical clinics to supplement bedside instruction were inaugurated through the efforts of Dr. Parker in 1841. Practical work in obstetrics began in 1853 while about the same time the chair in physiology and pathology was created and placed under the charge of Dr. Alonzo Clark, who had just completed a course of postgraduate study in pathology in Paris. In 1878 an event of special historic interest was the establishment of a student laboratory for instruction in pathology with Francis Delafield as its director. A nominal union between the College of Physicians and Surgeons and Columbia College was ratified in June, 1860, but it was not until November, 1891, that the actual union of the two institutions took place. The course of study was at least two years of five months each until 1878, when the time was extended to seven and one half months. In 1887 the course was again extended to three years of eight and one half months each until 1894, when four years of eight and one half months each were required. This centennial anniversary will be celebrated at the coming commencement of Columbia University, June 10-12. A special number of the *Columbia University Quarterly* is largely devoted to the medical work containing leading articles by Profs. L. Emmett Holt, Frederick S. Lee, Walter B. James, Francis Carter Wood, M. Allen Starr and George S. Huntington. It is a valuable addition to the literature of historical medicine.

NORTH CAROLINA.

State Hospital Directors Meet.—At a recent meeting of the directors of the State Hospital for the Insane, Morganton, Dr. P. L. Murphy was reappointed superintendent, and Drs. John McCampbell and James K. Hall, assistant physicians.

Society Meeting.—At the annual meeting of the Haywood Medical Society the following officers were elected: President, Dr. Rufus L. Allen, secretary treasurer, Dr. J. Howell Way, and delegate to the state association, Dr. J. Rufus McCracken, all of Waynesville.

OHIO

Graduate School Opened.—The Graduate School of Cincinnati, whose teaching force is made up from the faculty of the Medical College of Ohio, with which it is connected, opens for its first session this spring.

Physicians Swindled.—It is reported from Akron, April 11 that about 30 physicians of that town have been swindled by two men who represented themselves to be agents for a collection agency and induced physicians to sign notes of \$100 each, entitling them to membership in the agency.

Election.—The annual meeting of the Akron Medical Club was held April 4 when the following officers were elected: President, Dr. Le Roy C. Eberhard, vice president, Dr. H. Irving Cozard, secretary, Dr. Edmund A. Weeks and treasurer, Dr. James G. Grant. This club is organized along the line of promoting the social side of medical life.

Milk Commission for Toledo.—The president of the Academy of Medicine of Toledo and Lucas County has appointed Drs. William C. Chapman, Charles W. Moots and Homer H. Heath to serve with Dr. I. Howard McVay representing the Toledo Homeopathic Society, the secretary of the Woman's Clubs and the secretary of the Chamber of Commerce to secure a better milk supply for Toledo.

Personal.—Dr. O. M. Pinney, Madisonville, has been appointed by the Presbyterian Board of Foreign Missions as medical missionary to Benito West Coast of Africa. Dr. Adolphus W. Foertmeyer has been appointed receiving physician at the City Hospital, Cincinnati, vice Dr. A. E. Osmond, resigned. Dr. John B. Woodworth, Delaware, secretary of

the Delaware County Medical Society, has resigned and left for Texas.

PENNSYLVANIA.

State Hospital Burned.—On April 8 the State Hospital for the Insane, Norristown, was destroyed by fire. A majority of the patients have been transferred for temporary lodgment and care to the insane department of the Philadelphia Hospital.

Society Meeting.—The North Penn Clinical Society, composed of physicians practicing in towns along the North Penn Railroad, was organized at Quakertown, March 13. The following officers were elected: President, Dr. Josiah E. Bauman, Telford, vice presidents, Drs. Oliver H. Fretz, Richland Center, and John J. Ott, Pleasant Valley, secretary, Dr. Walter H. Brown, Richlandtown, assistant secretary, Dr. Francis A. Borzell, Cressman, and treasurer, Dr. Alfred E. Fretz, Sellersville.

The Medical Board Bill.—The Bowman bill remains in the house judiciary general committee in the hope that a change of sentiment will take place in favor of the measure. The bill was introduced primarily to elevate the standard of Pennsylvania medical practitioners. There are 54 civil divisions in the United States, including Porto Rico, Hawaii and the Philippines, of which 30 have single medical boards while only 12 have three boards. In Pennsylvania there are at present three boards, regular, homeopathic and eclectic, each of which examines graduates of medical colleges belonging to its particular school. If an applicant fails to pass one board he can apply for an examination before another board and so receive a license. Representative Bowman's bill provides for a single examining board of 10 physicians selected from the regular, the homeopathic, the eclectic and the osteopathic schools, to be appointed by the governor, no school having a majority of the entire board. The objectors to the bill say that the examining boards should be composed of 12 members, three representatives from each of the four schools. The regular profession insists that this should be left to the discretion of the governor.

Philadelphia

Cerebrospinal Meningitis.—The presence of a number of cases of cerebrospinal meningitis in different sections of the city during the last two weeks has caused alarm among health officials. Since April 6, 14 cases of the disease have been reported to the bureau of health and 4 deaths from the disease have been reported.

Hospital Applies for Aid.—The Hospital of the Woman's Medical College of Pennsylvania has issued an appeal for aid because it is doing a great work for the sick poor and yet is hampered by insufficient temporary quarters, having no private rooms as a source of income and no endowment fund. The hospital asks for money and annual subscriptions for the endowment fund or for the building fund.

Personal.—Dr. J. William White, professor of surgery at the University of Pennsylvania, has been elected advisory surgeon of the Pennsylvania Railroad Company. Dr. White will have supervision of the medical corps of the system. Dr. William W. Keen has been elected an honorary member of the German Surgical Society. He is at present in Berlin, a delegate to the surgical congress being held there.

Hospital Cornerstone Laid.—On April 9 occurred the laying of the cornerstone of the new Frankford Hospital. Previous to the ceremony addresses were made by James S. McMasters who presided, Representative Samuel Christian, Congressman W. W. Foulkrod and Dr. J. Baker Laird. Isaac Schlechter, chairman of the building commission, laid the cornerstone. The new building will be a two-story brick structure with provision for the addition of two stories.

TENNESSEE

Graduation.—The fifty-sixth annual commencement exercises of the University of Nashville, Medical Department, were held March 29 when a class of 52 was graduated. Chancellor James D. Porter of the university presided, and Dr. L. M. King delivered the faculty address.

Society Meeting.—At the annual meeting of the Nashville Academy of Medicine and the Davidson County Medical Society held at Nashville April 2, Dr. George W. Crile, Cleveland, Ohio, delivered the address of the evening on "Direct Transfusion of Blood." The following officers were elected: President, Dr. Marvin M. Cullom, vice president, Dr. Rufus F. Fort, secretary, treasurer, Dr. Holland M. Tigert, and delegates, Drs. William D. Haggard, John A. Gaines and Simeon S. Crockett, all of Nashville.

TEXAS

Fire Losses.—On March 16 the office of Dr Robert S Foster, Northrup, was destroyed by fire with a loss of more than \$1,000.—The Denton County pest house, five miles south of Denton, was burned April 1, with a loss of about \$300

WISCONSIN

Smallpox.—It is reported that there are 40 cases of small pox at Manawa, a number of cases have also developed at Roy alton

Personal.—Dr and Mrs Victor F Marshall, Appleton, sailed for Europe on the *Minnetonka* from New York, April 6.—Drs Frank P Donahue and Oscar Lutz, internes at the Emergency Hospital, Milwaukee, have resigned.—Dr Joseph Lewis, Milwaukee, who has been ill at the Hanover Hospital for three months, has recovered.

Tuberculosis Sanatoria.—Dr Chester A Paull, superintendent of the new State Sanatorium for Tuberculosis, Wales, reports that the sanatorium will be opened about June 1, when from 80 to 100 patients can be accommodated.—The Milwaukee Sanatorium for Tuberculosis Association has taken possession of its property on the Blue Mountain Road. Plans for two pavilions have been completed and the administration building is now ready for use

Hospital Notes.—Drs William M. Gratiot and H D Ludden have opened a hospital at Mineral Point.—A meeting was held at Portage, April 6, to discuss the matter of a hospital for that city and to form an organization. Dr William J Thomson was elected permanent secretary, and the ways and means of defraying the cost of a hospital were discussed. The consensus of opinion was that a hospital to meet the needs of Portage should cost from \$15,000 to \$20,000

GENERAL

Tuberculosis Sanatorium in Porto Rico.—The tuberculosis sanatorium founded at San Juan by the Anti Tuberculosis League of Porto Rico was dedicated April 5 by Governor Winthrop

New Medical Society.—The Mexican physicians in Monterey, Mexico on April 4, effected a permanent medical organization to be known as the Nueva Leon Medical Society. A constitution and by laws were adopted.

Havana Physicians Protest.—The physicians of Havana held a meeting recently and entered a protest against the activity of Governor Magoon in licensing two American physicians to practice medicine in Havana who had not first passed an examination in the University of Havana, as required by law

National Boards of Health Conference.—The fifth annual conference of State and Territorial Boards of Health with the Public Health and Marine Hospital Service will be held in Washington, D C, May 31, 1907. These conferences are convened in accordance with the act of Congress approved July 1 1902, "increasing the efficiency of the Marine-Hospital Service." The subjects to come before this conference for discussion will be "Sanitary Supervision of Milk Supplies," "Malaria its Geographical Distribution," and "Bacillus Carriers." The last named important subject is attracting much attention at present

American Pediatric Society.—This society will hold its nineteenth annual meeting at Washington, D C, March 7 & 8 1907. The headquarters and meeting place will be the Arlington Hotel. Among the subjects on which papers will be read are "The Caloric Value of Modified Milk," Dr Maynard Ladd, Boston, "Cane Sugar Feeding in Its Relation to Some of the Disorders of Childhood," Dr Charles G Kerley New York, "Kernig's Sign in Infancy, a Study of Two Thousand Cases," Dr John Lovett Morse Boston, "Bacteriology in Meningitis," Dr F S Churchill Chicago, "Grip Meningitis," Dr Samuel S Adams Washington, "The Best Treatment in Chorea," Dr John Ruhrh Baltimore, "Etiology of Infantile Atrophy," Dr A H Wentworth Boston. Further information may be had from the secretary, Dr Samuel S Adams, 1 Dupont Circle Washington D C

Association of American Medical Colleges.—The annual meeting of this association will be held in Washington May 6. The president's address will be given by Dr George M Kolber Washington. The topics taken up will be "Giving Credit for Work Done in Literary Colleges, the Combined Course" by Dr Egbert LeFevre New York, "The Advancement of Medical Education" by Dr Murray Colt Motter Washington, "Should Examinations for Licensure be in Two Parts and How Shall They be Conducted?" by Dr William J Means Columbus Ohio, "Teaching Internal Medicine" by Dr William S Thayer Baltimore, "Teaching Materia

Medica, Pharmacology and Therapeutics," by Dr Torald Sollmann, Cleveland, Ohio, "Teaching Anatomy," by Dr Frank S Baker Washington, and "When Shall students Begin to Attend Clinics?" by Dr Frank E Bunts, Cleveland, Ohio

American Academy of Medicine.—The thirty second annual meeting will be held at Atlantic City, N J, June 1 and 3, 1907. The secretary is Dr Charles McIntire, Easton, Pa. Some of the papers on the program are to be on the following subjects

President's Address A Medical Career and the Intellectual Life Dr Casey A Wood, Chicago
The Communal Life of Physicians Dr Leartus Connor Detroit
The Housing Problem Drs S A Knopf and Gertrude C Light New York City
The Effect of Child Labor on Physical Development Dr Alfred Friedlander Cincinnati
The Superiority of the Playground to the School room, Dr Woods Hutchinson Arrowhead Cal
The Soldier as a Total Abstainer Dr J W Grosvenor Buffalo
Insurance for Defectives Dr James A Spaulding Portland Me.
State Examining Boards Dr Henry Beates Jr Philadelphia
Relations of the Medical and Legal Professions to the Public, Dr T H Shastid, Marlon Ill
Legislation to Promote Preventive Medicine Dr Benjamin Lee Harrisburg
A National Department of Health Dr J Pease Norton New Haven
Criminal Abortion Dr Henry W Cattell Philadelphia

Obliterating a Yellow Fever Focus in Cuba.—Dispatches published in the reports of the U S Public Health Service give an account of the prompt and energetic measures adopted to suppress a focus of yellow fever that has been discovered in Havana Province, Cuba. The reports show that the disease in the single case reported was contracted at a plantation in the vicinity of Nueva Paz, a town of 2,000 inhabitants situated about 45 miles southeast from Havana. The patient, a Spaniard, who has been removed to Las Animas Hospital, Havana, arrived in Cuba last December, and after ten days' stay at Havana, went to Nueva Paz, where he remained continuously until taken sick. Dr Stansfield of the Public Health and Marine-Hospital Service reports that a disinfecting and oiling brigade of forty men, under experienced supervision, has been sent to Nueva Paz to exterminate mosquitoes, and that the work of sanitation will be extended to all places in the vicinity. Major Kean, adviser to the Cuban Sanitary Department, stated, April 2, that Havana is free from yellow fever, and inasmuch as the present case was imported, there is no reason to fear infection in that city. The only other case of yellow fever, a fatal one, reported in Cuba during the present year occurred in January at Santa Clara, capital of the province of the same name

CANADA

New Western University.—Alberta is to have a provincial university at Strathcona

Cremation.—Cremation is growing in Montreal, where is located the only crematory in Canada. There were 33 cremations from the commencement of operations in 1904 until April 2, 1906 and 13 from that date until Feb 28 1907. Prior to the establishment of the McDonald crematory there had been 12 by the Mount Royal Cemetery

Hospital News.—The late Mrs Peter Redpath of Montreal left the Montreal General Hospital \$40,000.—A new quarantine hospital will soon be ready for occupation in Winnipeg Man.—A psychiatric clinic is to be established in connection with the proposed new general hospital for Toronto. It is intended that it shall occupy a separate building; have accommodation for 100 patients and treat acute cases of mental disease

Checking Consumption in British Columbia.—The annual meeting of the Anti Tuberculosis Society of British Columbia was held in Victoria April 2. Dr Fagan the municipal health officer of British Columbia who has the matter of the erection of a sanatorium in charge announced that there are nearly sufficient funds in sight to proceed with building operations. He has collected \$10,000 in Vancouver where the medical profession alone subscribed \$2,500. About \$10,000 is still needed before the necessary \$30,000 is secured

Personal.—The Manitoba Board of Health has been appointed as follows: Dr R M Simpson Winnipeg chairman, Drs John M Eaton John A Macdonald F L Schaffner and Gordon Bell.—It is announced that the government will appoint Dr Thompson M P of Dawson commissioner of the Yukon at a salary of \$5,000 with \$6,000 for living expenses.—Dr Andrew Laidie of Toronto was assaulted by the father of a former patient who died of appendicitis. The father of a heavy teamster's whip was the instrument. The patient has lain unconscious at his home

April 8—Major Leonard Vaux, M.D., P.A.M.C., Toronto, will be Canada's representative with the imperial army at Aldershot and later on at the Royal Army Medical College at London. He will take up a course for the next year in bacteriology and hygiene—Dr Halpenny, Winnipeg, is doing graduate work at Johns Hopkins University

FOREIGN

A Hospital on the Mount of Olives—The foundation stone of the new German hospital on the Mount of Olives was laid March 31, 1907. The Sultan of Turkey gave the land

A New Medical Mission in India—A new medical mission has been started in Parbhani, in the Nizam country, by the United Free Church of Scotland. The Murray Mitchell Hospital and dispensary buildings are to be erected at this place

Appropriations for Scientific Purposes in Germany—Among the appropriations recently voted by the German parliament is \$50,000 for repression of typhoid fever and \$30,000 for tuberculosis, \$10,000 for study of sleeping sickness, \$17,500 for the approaching International Congress for Hygiene at Berlin, September 23-29, \$25,000 for research on syphilis, \$6,500 for investigation of the statistics of accidents and \$10,000 for combating infant mortality

The "Preventive" Theater—In order to continue the anti-venereal campaign, Le Valher and Nigel of Paris have organized evening entertainments at a small theater, rue Saint Denis 133. "The Imitation" is the name given to the entertainment. First there is a two act play called "The Imolated," the plot turning on a case of syphilitic sterility. The second part is a lantern talk on syphilis, with numerous views. The organizers of the show do not seem to be physicians, but they admit physicians free on presentation of their visiting cards

Pharmacy in Turkey—The United States Consular and Trade Reports state that there are 400 pharmacists in Constantinople and quotes a local pharmacist as follows: "Physicians, with the fear of having their prescriptions transformed by doubtful dispensers, are wont to order medical specialties which offer guaranties of careful preparation." Although this may be an exaggerated view, there is, nevertheless, the Reports state, a growing demand for medical specialties. As late as ten years ago advertising had little or no effect on the sale of such specialties but this is no longer the case, and the importance of keeping before the public in an intelligent manner by means of advertising in the principal local journals, by posters in the streets, stations and public places, is increasing and becoming recognized by those interested.

Training School for Disinfectors—In Prussia during 1905 about 64 official nine day courses of lectures on practical disinfection were given at 17 different points, 533 persons attended the lectures, and 533 passed the examinations and received certificates as officially tested disinfectors. Besides the above courses a number of three day courses were held for nurses, and about 200 nurses were thus trained for the disinfecting service especially for continuous bedside disinfection while the licensed disinfectors were trained especially for the terminal disinfection. Every three years the licensees must submit to further tests and take another course of lectures at the end of six years. Steam disinfection apparatus are preferred to formalin apparatus as a rule. The *Münch med Wochschr* mentions further that applicants must be under 45

Quinin Tannate Candy for Children—The Academy of Medicine, Rome Italy recently passed a resolution asking the government to have quinin tannate in the form of chocolate drops, distributed for the use of children in malarial regions. Zeri Conetti and others related very favorable experiences with it. Contrary to other preparations of quinin the tannate is borne well even when there is considerable vomiting and diarrhea is favorably influenced. It is evidently tolerated better by the intestinal canal as it is less bitter and less toxic. A child affected with hemoglobinuria every time quinin was given under any other form tolerated the tannate chocolate drops and was thus soon cured of malaria. Viale proclaimed its advantages as long ago as in 1852. The vote was, therefore taken asking that the tannate in this form be sold at cost price or distributed free to children like the other preparations of quinin for adults

Plague in India—Consul General Michael at Calcutta reports that the plague mortality is increasing in the Punjab at the rate of 1,000 deaths a week. He also quotes the report of the health officer of Calcutta that experiments at inoculation in India have been somewhat discouraging. In Calcutta an

offer of 16 cents each to all who had themselves inoculated had so little effect that only 101 inoculations were made during the year. Attempts to exterminate the rats were equally disappointing, although 4 cents each were offered for live rats. Altogether about 100,000 rats were accounted for, but this does not seem to have made much impression on the rat population. All species of rats seem to be liable to the disease, so that attempts at destruction must include all kinds. The extermination of the rodents and the consequent abolition of plague is likely to be a difficult task which will take a generation or two, but it should not be deemed hopeless

Improved Records of Criminal Statistics in France—According to new regulations, the statistics of crimes in France will in future strive to take account of the physical conditions, the individual conditions and the social conditions which are at the basis of a given crime, so far as they can be determined. The physical conditions include climate, nature, soil, season, the individual, age, sex, origin, profession, etc., and the social, density of the population, poverty, wealth, etc. Further than this, each record is obliged to mention whether the offense had been committed under the influence of liquor, and whether the criminal is a habitual or occasional drinker. The statistics for 1905 show that 2,204 criminals were declared to be irresponsible. In issuing his orders the minister of justice urged research into the past of the criminal, his heredity, his education, environment, the causes of his fall and means of redemption. If by this means, he said, the magistrate, in concert with the medicolegal experts, can work back from the crime to its pathologic origin, justice will be enlightened and the cause of science promoted. An editorial in the *Semaine Méd*, from which we quote the above, states that the statistics collected henceforth in France will be more complete and hence more valuable than those of any other country

Resignation of Danish Board of Health—Meyer writes from Copenhagen to the *Münch med Wochschr* stating that on March 5 the Royal Board of Health (Kgl. Sundhedsamt) sent in its resignation as a body, signed by all the members of the board. This body was organized in 1803, and has charge of all sanitary and public health matters, and its members serve without pay. During the last five years it has been entirely ignored by the minister of justice, who has drawn up bills, made appointments, etc. without consulting the public health office in any way. The bill for repression of venereal disease, recently described in these columns page 1119, was drawn up and passed without consultation with it, as also the bills in regard to repression of tuberculosis and other health matters. The board presented a detailed list of grievances to the king in an official communication three months ago, to which the minister replied, on the floor of parliament, in sarcastic terms. Nothing remained for the members of the board but to resign which they have accordingly done. As no other physician will accept a position on the board as matters now stand, the country is without an official health bureau. The lack of expert medical supervision is evident Meyer says, in the antivenereal law mentioned above, especially its sanitary features. The medical profession fears that some of the provisions of the law will shake the confidence of the patient in his physician whom he will look on more as a police officer than as a confidant and friend

Half a Million Vaccinated in Paris in Fifteen Days—France always has a number of cases of smallpox each year at different points, in 1904 there were 1,000 cases in 15 departments, but the populace has never taken this condition of affairs seriously, and the measures requiring vaccination have never been strictly enforced. A few cases of smallpox occurred recently at Dunquerque, and three out of the four nurses who came in contact with the first patient died. The small epidemic was promptly arrested but the Paris press wrote it up and a remarkable smallpox scare resulted. The people crowded by thousands to be vaccinated, Chantemesse estimates that nearly 500,000 were vaccinated during the first two weeks. The *Académie de Médecine* in commenting on this curious page of history in this year of our Lord 1907, called attention to the drawbacks of such hasty, wholesale vaccinations. The law in Prussia forbids more than 130 vaccinations at one sitting, and in Baden no more than 150 can be vaccinated in one day. The necessity for legislation in France compelling vaccination of the floating population, sailors, day laborers temporarily employed and the like, was earnestly pleaded by Kelsch. The power of the press, he added has been illustrated once more by this "delirium for vaccination" which it induced by writing up the half dozen cases at Dunquerque, while the populace has never been roused from its inertia before by the thousand odd cases occurring on all sides every

year Men, women and children fought for the vaccine which the week before they had regarded with sublime indifference, as will probably be the case also a month from now Kelsch commented further on the aid which the press might render to sustain the efforts of physicians in keeping alive this fear of smallpox which is the beginning of wisdom

LONDON LETTER.

(From Our Regular Correspondent)

LONDON, April 6, 1907

The Use of Alcoholic Beverages

A controversy on this subject has been started in the medical and in the lay press by certain eminent members of the profession Apparently, they are dissatisfied with the pronouncements, which have recently been made by men equally eminent, deprecating almost entirely the use of alcohol and the marked tendency to its disuse which has been much in evidence of late Sir Victor Horsley, who is the most prominent medical advocate of the profession, recently stated at the Toronto meeting of the British Medical Association that alcohol is being rapidly superseded by milk in London hospitals The following manifesto has been issued and signed by some of the most prominent physicians and surgeons "In view of the statements frequently made as to the present medical opinion regarding alcohol, we think it desirable to issue the following statement, which we believe represents the opinions of the leading clinical teachers as well as the great majority of medical practitioners Recognizing that in prescribing alcohol, the requirements of the individual must be the governing rule, we are convinced that in disease alcohol is a rapid and trustworthy restorative In many cases it may be described as life preserving, owing to its power of sustaining cardiac and nervous energy, while protecting the wasting nitrogenous tissues As an article of diet, we hold that the universal belief of civilized mankind that the moderate use of alcoholic beverages is, for adults, usually beneficial, is amply justified We deplore the evils arising from the abuse of alcohol But there is nothing, however beneficial, which does not by excess become injurious" It need not be said that such a manifesto has not been allowed to pass unchallenged by the opponents of alcohol, who include names in the profession equally eminent A counterblast has been started in the *Lancet* by Sir James Barr and others Sir James Barr states that he is anxious to get reliable information as to the power of alcohol to sustain cardiac and nervous energy He prescribes it simply as a sedative and antispasmodic to paralyze the vasomotor system, much in the same way as he does nitroglycerin We are only at the beginning of what threatens to be a very hot controversy It is a curious comment on our boasted progress that the leaders of the profession should be so diametrically opposed regarding the use of a remedy as old as civilization, the experience of the use of which is incalculably great and concerning which an enormous number of experiments on man and animals have been made It is unfortunate that the controversy should have extended to the lay press, but this was rendered inevitable by the publication of the manifesto there Once more the differences of the profession will become a subject of jibe for the public. Worse still, unfounded imputations have begun to be cast on the signers of the manifesto, such as How many of the signers hold brewery or distillery shares? and, How many cases of Scotch whisky does the manifesto represent?

VIENNA LETTER.

(From Our Regular Correspondent)

VIENNA, April 3, 1907

Damages Recovered for Sepsis Resulting from Having Corns Cut in a Public Bath.

A remarkable case was decided recently by the court of appeals A merchant in the prime of life asked for damages on the ground that he had been infected when having his corns cut in a bath by the men paid by the proprietors of the bathing establishment to perform this small operation on the visitors It appeared that the possibility of having the corns cut by a "specialist" attracted many persons to that special bath and that the merchant in question, who was operated on in the bath soon afterward complained of pain in his leg, which became swollen and painful Although medical aid was called in, sepsis was inevitable and the leg had to be amputated below the knee. The court decided that the proprietors were responsible for their employees and that the fact of medical aid having been sought at once proved clearly that there had been no negligence on the part of the sufferer Therefore, the claim of the plaintiff was justified and he was awarded damages to the amount of \$2,000 The proprietors were at the same time severely reprimanded for not carrying out the city

ordinance in regard to bathing establishments, which requires the presence of a medical man during certain hours of the day on the premises for the purpose of controlling all instruments and apparatus used for massage, inhalations etc

Women Eligible to the Posts of Senior and Junior Hospital Officers

By the appointment of a woman to the post of "Secundir-arzt" in a children's hospital, a new and important step has been taken by our very conservative hospital administration, which hitherto has constantly ignored the presence of fully qualified medical women and the useful work done by them in their unofficial positions as "Aspirant" or "Hospitalant," both expressions meaning nothing more than "a tolerated guest" The prejudice was so strong in many quarters that even Professor Albert, the famous surgeon, did not allow female students to work at his clinic. Several petitions have been forwarded to the ministry of the interior at different times, but the rules of the Vienna University give so much independence to both the professors and the students that the minister felt unable to interfere The increased recognition accorded to the work done by women physicians has prompted first one and then another of the holders of the university chairs to appoint a medical woman as their assistant, and at last the medical women have been found to do just as valuable work as the men The government now makes no further distinction between the male and female sex when it is a question of merit

Investigations into the Hygienic Conditions of School Children

The institution of medical inspectors of schools, only a recent addition to the administration of our schools, has already rendered good service in investigating the reasons of the insufficient physical fitness of many children, especially in large towns One of the foremost causes has been found to be insufficient sleep, more than 20 per cent of all the children go to bed after 10 p m, and the difference between the actual length of sleep and the time spent in bed ran up to one hour and forty minutes or 20 per cent of the time This is explained partly by the bad habit of keeping the children awake, or by unhygienic surroundings Only from 30 to 40 per cent of the children sleep alone, the remainder have to share the bed with one or two or even with more persons Bathing is a luxury which only 10 per cent of the children can have at home The school baths are doing very good work in this respect, and bathing facilities are now installed in nearly every school In only very few class rooms can all the windows be opened, in most school rooms the windows have to be closed because of the street noise The bad effects of short sleep, bad air and also of inadequate nourishment combine to make the children anemic and less vigorous The remedies recommended by the medical inspectors are Better ventilation, by opening the windows every hour for at least ten minutes, opening school at 9 instead of 8 a m, and distribution of free meals to those children who need it

Association News

OFFICIAL CALL

THE FIFTY EIGHTH ANNUAL SESSION OF THE AMERICAN MEDICAL ASSOCIATION, TO BE HELD AT ATLANTIC CITY, N J, JUNE 4, 7, 1907

To the Officers and Members of the Constituent State and Territorial Associations of the American Medical Association

The fifty eighth annual session of the American Medical Association will be held at Atlantic City, N J, on Tuesday, Wednesday, Thursday and Friday, June 4, 5, 6 and 7, 1907

THE HOUSE OF DELEGATES

The House of Delegates of the American Medical Association will convene at Atlantic City, N J at 10 a m on Monday, June 3, 1907 The representation in the House of Delegates of the various constituent associations for the years of 1907, 1908 and 1909 will be as follows

Alabama	3	Montana	1
Arizona	1	Nebraska	1
Arkansas	1	New Hampshire	1
California	3	New Jersey	2
Colorado	2	New Mexico	1
Connecticut	2	New York	11
Delaware	1	Ontario	1
Dist. of Columbia	1	North	1
Florida	1	North	1

Georgia	2	Oklahoma	2
Hawaii	1	Oregon	1
Idaho	1	Pennsylvania	8
Illinois	7	Rhode Island	1
Indiana	4	South Carolina	2
Iowa	3	South Dakota	1
Kansas	3	Tennessee	2
Kentucky	3	Texas	5
Louisiana	2	Utah	1
Maine	1	Vermont	1
Maryland	2	Virginia	1
Massachusetts	6	Washington	3
Michigan	4	West Virginia	1
Minnesota	2	Wisconsin	3
Mississippi	2	Wyoming	1
Missouri	4	Philippine Islands	1
Ohio	6		

The twelve sections of the American Medical Association, the Medical Department of the Army, the Medical Corps of the Navy and the Public Health and Marine Hospital Service are entitled to one delegate each

FIRST GENERAL OR OPEN MEETING

The first General Meeting, which constitutes the opening exercises of the scientific functions of the Association, will be held at 10 30 a m, Tuesday, June 4

REGISTRATION DEPARTMENT

The Registration Department will be open from 8 30 a m until 5 p m, on Monday, Tuesday Wednesday and Thursday June 3, 4, 5 and 6, and from 9 to 10 a m on Friday, June 7

WILLIAM J MAYO, President

GEORGE H SIMMONS, General Secretary

THE ATLANTIC CITY NUMBER

The Annual Professional Writeup with Programs and Full Details of the Session

The May 4 issue of THE JOURNAL will be the annual special number giving the preliminary programs of the sections, lists of headquarters, hotels, meeting places, railroad rates, excursions and other data of interest to those who will attend the fifty eighth annual session of the American Medical Association in Atlantic City, N J, June 4 to 7, 1907 Between 50 000 and 60 000 copies of this special edition will be distributed Any one who has data concerning special parties, plans for stopovers excursions and other matter of interest to the members should send in this information at once

To answer questions that are being asked about headquarters for the various sections we repeat from THE JOURNAL, February 23 the following list

HEADQUARTERS

GENERAL HEADQUARTERS Marlborough Blenheim
PRACTICE OF MEDICINE Hotel Dennis
SPECIAL AND ANATOMY Hotel Chalfonte
OBSTETRICS AND DISEASES OF WOMEN Haddon Hall
DISEASES OF CHILDREN Hotel Traymore
NERVOUS AND MENTAL DISEASE Hotel Brighton
OPHTHALMOLOGY Hotel Seaside
LARYNGOLOGY AND OTOTOLOGY Hotel Strand
PATHOLOGY AND PHYSIOLOGY Hotel Shelburne
BACTERIOLOGY AND SANITARY SCIENCE Hotel St Charles
PHARMACOLOGY AND THERAPEUTICS Hotel Marlborough
CLINICAL MEDICINE AND SURGERY Hotel Marlborough
STOMATOLOGY Hotel Traymore

General headquarters for registration, information, commercial exhibits and the Scientific Exhibit will be on Young's Pier

Atlantic City is preparing to give those who attend the coming session in June even better accommodation than heretofore, there being more hotels and larger ones than when the Association last met in Atlantic City Special attention is being given to locating the section headquarters in hotels directly on the beach front and contiguous to the Boardwalk The section meeting places are being grouped as closely together as rooms providing commodious accommodation can be obtained It will be the endeavor of the Trustees' committee, ably assisted by the auxiliary committee, to provide for the members of the Association the greatest amount of comfort possible within a short radius, and at a minimum expense

The secretary of the Committee on Hotels is Dr W E Tomlin 1616 Pacific Avenue

Correspondence

Certain Medical Aspects of Jury Trials

PROVIDENCE, R I, April 15, 1907

To the Editor —Whenever any distinct fault with a public institution becomes evident to the medical profession, it becomes the duty of this profession to manifest its views to the proper authorities and to call for a remedy The methods of certain commonwealths in the disposition of their convicts, the relations of convict and ordinary labor, the hygiene of prison life—all have been passed in review of late and discussed by professional and lay writers, but as yet the conduct of jury trials has not been regulated or to any extent criticised

Now it must be evident to any fair minded person that 20, 30 and even 40 hours of constant discussion and deliberation is too much for any person, that no person after the lapse of such a period of thought is capable of sound judgment, and that any issue decided by jurors who have passed their usual periods of repose and sleep is decided by men with warped judgment, tired minds and muddled intellects Let any physician ask himself what his judgment would be worth after 20 hours of deliberation on any one subject Let him at such a time try to recall even fundamental questions on professional subjects Would his views on any subject be worth hearing, or would he dare offer any opinion on which human life or liberty were at stake? Let the profession tell if the jury in any hard fought criminal case is capable of sound judgment in such distinctly unhygienic surroundings as invariably obtain I wish to protest with all my power against such conditions and to suggest a remedy, and I predict that thinking people will in time see the *rational* of this philosophy It is not necessary to quote from neurologists as to the ability of the human mind to stand mental strain This is only too evident to any intelligent person Why, then, should not juries, on whose judgment hangs the question of life or death, of success or ruin and of financial loss or gain, conduct their deliberations in a sensible manner, with suitable provisions for rest, with regular meals and with stated periods of sleep They will do their work better and in a shorter time, and we shall read no more accounts of haggard men, with voices cracked and high pitched from exhaustion, wrangling and striving to arrive at a conclusion which might have been reached long before, were the jurors in better physical condition The remedy A day of 12 hours, or, at most, 14 One half hour recess after each three hours of work, with provision for a change of air in the work room and for a short walk in fresh air A bedroom with cots for sleeping, with regular hours allotted, and bathrooms for those who would use them Let the public understand that under such conditions its welfare would be better served, let the prisoner know that under present conditions his sentence may be unjust and that under proper conditions justice is more sure, and let a jury take four days of 12 hours each to decide a murder case rather than one of 40 hours The medical profession should discuss this important matter and, if it sees fit, urge on legislators and on the people a change as important as it is radical Then no innocent man will suffer through the personal fatigue of an overtired jury, and jury trials will be purged of at least one of their undesirable attributes

W LOUIS CHAPMAN M D

Disclaimer for "American Medical Syndicate"

PHILADELPHIA, April 13, 1907

To the Editor —I am informed that one or more persons in Washington, D C, are endeavoring to interest physicians in the "American Medical Syndicate," whatever that may be, and are stating that I am largely interested in it To the best of my recollection I never heard of the syndicate before, or of any one connected with it

H A HANE

Pharmacology

CAMPHO PHENIQUE

Report of the Council on Pharmacy and Chemistry

The following report was submitted to the Council on Pharmacy and Chemistry by the subcommittee to which Campho Phenique had been assigned

To the Council on Pharmacy and Chemistry—Campho Phenique, sold by the Campho-Phenique Co., St. Louis, Mo., is claimed to be composed of phenol 40 per cent., and camphor 51 per cent.

Examination of specimens, purchased in the open market, made under our direction, demonstrate that the statements made in regard to the composition are not true. Instead of containing 49 per cent of phenol (carbolic acid), the analysis showed that it contains not more than 20 per cent. Instead of containing 51 per cent. of camphor, the analysis demonstrates that the amount of camphor is not more than 38 per cent. Besides phenol and camphor, a third substance was found which proved to be liquid petrolatum and to be present to the extent of 38 per cent or more.

Since the statements made in regard to the composition of Campho Phenique are deliberate misrepresentations of the facts, it is recommended that the article be not approved.

Besides Campho Phenique, the above mentioned firm also sells a preparation labeled Campho Phenique Powder. While no statement in regard to the composition of this product is made on the label or in the literature, such expressions as "Campho Phenique in a powdered form" and "Powdered Campho Phenique" lead to the inference that it has essentially the same composition as that stated for the liquid preparation. An examination of a specimen of Campho Phenique Powder purchased in the open market showed that 92 per cent of it was a talcum like inorganic substance. The remaining 8 per cent. consisted chiefly of camphor with a small amount of phenol.

In view of the fact that Campho Phenique Powder contains very little phenol, but instead consists chiefly of an inorganic talcum like substance, its name is misleading and deceptive. It having been shown that Campho Phenique Powder corresponds to a camphorated talcum powder, the claims that it "has no equal as a dry dressing," that it is "absolutely superior to iodoform," and that it has, "all the excellent properties of aristol and iodoform," are unwarranted. It is recommended that the article be not approved, and that this report be published.

The recommendations of the subcommittee were adopted by the Council, and in accordance therewith the above report is published.

W. A. PUCKNER, Secretary

The above report on a much advertised "ethical" proprietary medicine is worthy of the thoughtful consideration of the members of the medical profession, as it illustrates admirably some of the conditions connected with this proprietary medicine business.

THE FORMULA A FAKE

First it illustrates the fact that the published formulas of the "ethical" proprietaries are not always reliable. The Campho Phenique Company has been very willing to give out a formula, purporting their product to be 51 per cent. camphor and 49 per cent phenol (carbolic acid). Now, these two drugs will make a liquid mixture, and any druggist can make it and the mixture will have about the same consistency and appearance as Campho Phenique. But its effect differs decidedly from that of Campho Phenique. Some months ago a very intelligent physician, in discussing the proprietary medicine business said that in some cases physicians could not get druggists to make preparations which were as satisfactory as those which could be bought ready made. He cited Campho Phenique as an illustration. He said that he had used this preparation for burns, etc. but as he did not like to use preparations put up by companies about which he knew nothing, he asked his druggist to make the mixture in accordance with the published formula. The druggist's preparation was not satisfactory; it had a decidedly different effect from Campho Phenique, and so he tried another druggist. This druggist

also followed the published formula, but his results, too, differed materially from the proprietary article.

The various analyses that have been made show why the preparation put up by the druggist did not resemble that made by the company, since, according to the analyses, Campho Phenique consists of 40 per cent liquid petrolatum, which is an inert but soothing diluent, while instead of 49 percent of carbolic acid, as claimed, it really contains less than 20 per cent. This is an entirely different proposition. Now, if the physician referred to above will have his druggist make a mixture of 20 per cent of carbolic acid, 40 per cent of camphor and 40 per cent of liquid petrolatum, and will then compare this resulting compound with Campho Phenique, he will find that there is not much difference. Furthermore, he will realize that there is nothing either new or wonderful about the preparation. Camphorated oil and carbolized oil are both in common use. Campho Phenique is apparently simply a mixture of the two.

THE POWDER STILL WORSE

So much for the liquid. The powder seems to be something entirely different for according to the chemist's report, over 90 per cent of it is an inert absorbent, talcum like material. There is enough camphor and carbolic acid to give the powder an odor and thus mislead physicians, especially those who are in the habit of taking for granted that whatever statements nostrum manufacturers make are true. Perhaps it is a fairly good dressing for wounds—at least it will do no harm—but its name is misleading and deceptive. For all practical purposes it is essentially a camphorated talcum powder.

THE CAMPHO PHENIQUE COMPANY A "PATENT MEDICINE" CONCERN

The second interesting phase of this "ethical" proprietary is that it illustrates another point, i. e., that many of these articles are supplied to our profession by those who are not legitimate manufacturing pharmacists. The Campho Phenique Company of St. Louis, according to all reports, is owned and controlled by a gentleman named Ballard. This "company" supplies the medical profession with the preparations under consideration and also with chloro phenique and scrofonol. We are informed that this same Mr. Ballard is the principal owner if not the sole owner, of quite a number of "patent medicine" companies, such as Ballard Snow Liniment Co., Brown's Iron Bitters Co., Mayfield Medicine Mfg. Co., Smith Bile Beans Co., Swain's Laboratory, and several others. We learn from the wholesale drug trade lists that these various "companies" make and sell, beside the campho phenique preparations, Ballard Snow Liniment, Ballard's Herbine, Brown's Iron Bitters, Dr. Merriek's Pills, Richardson's Life Preserving Bitters, Smith's Bile Beans, Swain's All Healing Ointment, and several other patent medicines.

It is hardly necessary to make any further comments. The whole business is nauseating to those who know the actual conditions of this nostrum business and how our profession is being deluded. The Campho Phenique matter is not an exception; it is simply another illustration of these conditions.

The majority of "ethical" proprietaries are foisted on our profession either without any formula accompanying them, or with a "formula" that is a fake. The majority of the "ethical" proprietaries are manufactured and supplied to physicians, with instructions regarding their use, by men who bear the same relation to legitimate pharmacy that the veriest quack that ever swindled a credulous public bears to scientific medicine.

The Council on Pharmacy and Chemistry Encourages Reform

In explanation to manufacturers whose products have been refused recognition the Council directs publication of the following statement.

W. A. PUCKNER, Secretary

Some manufacturers, whose products have been rejected by the Council have taken issue with this action on the ground that they were not given sufficient opportunity to comply with the requirements. This can only arise from ignorance of the methods of the Council in these cases and seems to call for an explanation. In the first place, the Council does not like to reject any article, but prefers to see every product brought up

to its rules, and appreciates every attempt which manufacturers make in this direction. The rules have been public for over two years, which would seem ample time for compliance if the proper efforts had been made, but the Council stands ready to accept reforms even at this late date, and, indeed, at any time in the future.

When the Council determines to take up an article, this is generally assigned to a subcommittee, which prepares a report from the available evidence. This examination and report bear only on the article as it is marketed *at the present time*, and *not* on what it has been in the past or what it may become in the future, except that an unsavory past will naturally enjoin great caution in judging the present status of an article.

The report generally carries a recommendation whether the article shall be accepted or rejected, or final action delayed. A temporary suspension of judgment is recommended if the committee believes that the manufacturer is willing to reform objectionable features. If intentional fraud is discovered, the Council proceeds as it sees fit. If the objections are such as could be removed by proper reforms, the manufacturer is first informed of the decision of the Council, and the reasons therefor are given, generally in the language of the original report. This gives him an opportunity to file a reply or to take exception. If no reply is received, or if the reply contains nothing which could affect the decision of the Council, in the opinion of the committee, the article is considered definitely rejected, in its present form. The Council, however, is always ready to reconsider its decision, and to examine the article again, as soon as evidence is submitted that an honest effort has been made to remove the objectionable features. In other words, the fact that an article has been rejected does not mean that it will never be accepted. On the contrary, the Council aims to give all reasonable opportunity for reform. To this end, it has not thus far published its adverse findings as long as reform seemed possible (save in case of fraud and some other extreme instances). By furnishing to the manufacturers its specific reasons for rejection, it shows the direction in which reform is to be made. This, we believe, is all that should be necessary, and is as far as it would be wise for the Council to go. It can not be expected, and it would not be wise, for the Council practically to dictate the wording of the advertising matter, as has been asked by some, or to point out the very minimum of the changes which would be needed to bring a product up to the letter of the rules. A manufacturer must expect to be guided by the spirit of this movement. If he intends to adhere merely to the technicalities, he will be sure to infringe, sooner or later, intentionally or unintentionally. Such an attitude is not desirable. If he really wishes to reform he should plan to meet the objections of the Council to the full extent, and then ask to have his product reconsidered. Moreover, while the Council can not be expected to judge hypothetical cases, it stands ready to give an unofficial opinion as to whether contemplated changes will satisfy its requirements.

Another objection which is frequently raised is that the Council is arbitrary and autocratic in its interpretation of Rule 6. "No article will be admitted or retained of which the manufacturer or his agents make unwarranted, exaggerated or misleading statements as to therapeutic value." It is self-evident that questions of therapeutic value are often largely matters of opinion, and that the Council's judgment must then be more or less arbitrary. It is equally evident, however, that a line must be drawn somewhere, for disregard of the spirit of this rule has been mainly responsible for the "patent medicine" evil, and, indeed, suffices to class an article as a "patent medicine." The Council does its utmost to be absolutely fair in drawing this line, and whenever it judges that there is a sound basis for difference of opinion it inclines to give the manufacturer the benefit of the doubt, to discount his natural enthusiasm for his product. On the other hand, the manufacturer should remember that the Council is in a sense in a better position to judge therapeutic questions without prejudice for it has no interest in the matter, one way or the other except to arrive at the truth.

With every wish to be liberal however, the Council would not be doing its duty if it were to accept claims which have been disproved, or which are impossible, or excessively improb-

able. Doubtful claims can only be passed if a sufficient body of evidence from reliable observers is presented, to relieve the Council from responsibility, the quality and quantity of the required evidence being proportional to the improbability of the claims. Nor should manufacturers expect the Council to accept as evidence the statements of men whose sole contributions to medical literature consist in the endorsements of nostrums. Certain manufacturers seek exemption for statements of which they are evidently somewhat ashamed by publishing them as quotations or extracts from correspondents, articles or discredited text books. The Council can not encourage this subterfuge, and holds a manufacturer responsible for every statement which he publishes.

A Food Law Development.

In the JOURNAL, March 16, 1907, page 967, we called attention to an alleged prescription which is shrewdly advertised in news papers as a "simple home mixture which any druggist can put up. One of the ingredients, however, is a nostrum. This method of advertising is one way of evading the Food and Drugs Act.

A recent number of *Printer's Ink* directs attention to a similar case. The preparation in this instance has been widely exploited in the lay press, largely in advertisements made to appear as though they are reading matter, and is advertised as "Virgin Oil of Pine." *Printer's Ink* says:

"The preparation is put up in half ounce bottles and is recommended in connection with glycerin and whisky, in a stated formula as a remedy for coughs and colds, lung troubles, etc. Under the pure food law, a cough remedy containing two and a half ounces of simple ingredients suspended in eight ounces of whisky would have to be marked with a label stating the percentage of alcohol. In such a case the percentage would be large. Eight ounces of whisky would be entirely truthful and not at all alarming to the purchaser, but the law prohibits such a statement and the percentage of alcohol, if stated, would appear so high as probably to cancel a good many sales where purchasers read the truthful label. To overcome this disadvantage in marketing, the company advertises its preparation alone and the reader is given a formula whereby he can compound his remedy himself. As the formula may be advertised without any statement of percentage of alcohol and as only whisky is mentioned, the remedy is divested of what under other circumstances might appear to be a dangerous remedy. Whether or not this concern has evaded the law is a question for others to decide. It has certainly got around what would have been in its case a serious commercial drawback."

Medical Advertisements in Religious Papers

The following letter received from a correspondent emphasizes the importance and the value of physicians writing to editors of religious journals regarding their advertising pages. It also emphasizes the value of persistency.

To the Editor.—The question of the impropriety of religious newspapers accepting patent medicine advertisements is being discussed in your columns. Formerly the *Pittsburg (Pa.) Christian Advocate* contained such advertisements. Five or six years ago I corresponded with the editor in regard to the matter and he expressed his dissatisfaction with the affair and referred me to the business manager. I wrote many times to the latter party calling his attention to the fraudulent claims of some advertisements in the paper. To make a long story short for over a year this class of advertising has been discontinued. I do not know that my writing hastened the matter but I believe it contributed in a measure to the change. If the physicians who are readers of the various religious journals would take pains to enter their protest repeating such protests as often as might be necessary all such periodicals would in time be led to clean up their advertising columns.

Our correspondent's views emphasize the statement which has been repeatedly made in this department. No journal unless it is run exclusively and solely as an advertising sheet and is distributed gratuitously, will continue to carry advertising matter known to be objectionable to a large number of subscribers, in the face of repeated protests from those subscribers. That the religious papers have been great sinners along these lines in the past is well known. If physicians wish to enjoy reading a religious journal free from objectionable advertisements they have only to follow the example of our correspondent and write to the manager, and keep on writing until the paper is improved.

Medical Education and State Boards of Registration

Requirements for Practice in Japan.—Schwalbe reviews the requirements before physicians are admitted to practice in other countries, his article, "Zulassung im Auslande," appearing in the *Deutsche med Wochenschr* Nos 1 and 12. He states that according to a law passed last May, Japan requires certain qualifications and a license from the minister of the interior before an outsider can practice medicine. Four years of medical study are the minimum requirement, and the right is reserved to refuse or revoke the license in case the applicant is a minor, or deaf, dumb or blind, has been imprisoned or has been fined for medical malpractice. The law provides that each physician must keep a record of all his patients, with name, age, residence, occupation, disease and treatment. This record must be preserved for ten years. The law further prohibits false announcements in regard to a physician's ability, and it also prohibits advertising of secret remedies by physicians. According to a decree issued last September, reciprocity is allowed with foreign states which admit Japanese physicians to practice, conferring the license without examination on presentation of due credentials. Great Britain, to date, he says, is the only country whose physicians can thus be admitted to practice in Japan without further red tape. Schwalbe urges reciprocity agreements between Germany and suitable foreign states. He is a little premature in regard to Great Britain's reciprocating with Japan, we believe, as the question is still under advisement in parliament.

North Carolina—Higher Requirements at Wake Forest.—The Medical Department of Wake Forest College has adopted the resolution that beginning with the session of 1908-9, certificates of recommendation for advanced standing in other medical colleges will be given only to students who have completed the two year medical course and also the bachelor of science or bachelor of arts course. The two years work in medicine is elective in the BS degree and at the same time represents the first two years of work given in all first class medical colleges.

Virginia University Adopts Higher Requirements.—The medical faculty at its last meeting passed a resolution to the following effect. Beginning with the session of 1910 the minimum entrance requirements shall be the completion of two years of work in an institution of recognized collegiate standing, including satisfactory courses in physics, biology, inorganic chemistry and a language, preferably German. By "satisfactory" courses is meant courses more or less equivalent to those given in the college department of the University of Virginia. The administration of these requirements will be, as at present, in the hands of an academic officer, the dean of the university who passes on the entrance requirements of all the departments.

Medical Economics

THIS DEPARTMENT EMBODIES THE SUBJECTS OF ORGANIZATION CONTRACT PRACTICE INSURANCE FEES MEDICAL LEGISLATION ETC

Blue Earth County Organizes a Study Course.

Dr A G Liedloff, secretary of the Blue Earth County (Minn.) Medical Society, writes

"At the September meeting of our county society we decided to take up a regular course of study. Regular lessons were assigned and the chairman appointed members of the society as teachers to take charge of each meeting. It was also decided to meet weekly instead of monthly as heretofore.

"This plan was carried out with a fair degree of success, but, owing to the fact that one third of our membership live outside of town, it was not considered advisable to use the funds of the society nor to expect the regular officers of the society to do the work of the study class of which the physicians in the city receive the greater part of the benefit. Accordingly, we organized the Study Section of the Blue Earth County Medical Society, adopting a constitution and by laws and electing special officers. We began our work with 12 charter members, after issuing an invitation to all the members of the county society to join us. Our by laws provide that any member of any county society, on application may become a member of the study section. Dues are provided to cover actual expenses only. Meetings are held weekly at the office of the quiz master.

"The following outline for work has been placed in the hands of each member

March 6 Anatomy of the Chest	March 13 Diagnostic Methods
March 20 Larynx and Pharynx	March 27 Bronchial Tubes.
April 3 Diseases of the Pleura	April 10 Pneumonia.
April 17 Tuberculosis	April 24 Chronic Diseases of the Lungs
May 1 Anatomy and Physiology of the Heart.	
May 8 Pericarditis and Functional Diseases of the Heart	
May 15 Organic Diseases of the Heart	
May 22 Diseases of the Diaphragm	

A Firm Stand Against Contract Practice

Dr James J Hogan, secretary of the Solano County (Cal.) Medical Society, reports the results of the stand taken by his society on contract practice. Some years ago a number of fraternal orders having local lodges in Vallejo, the principal city in the county, adopted free medical services as one of the advantages of membership. Contracts were entered into with various physicians of the town at a nominal figure. Other organizations, seeing the advantages of such a plan also adopted it, until almost every organization in the city was offering free medical services to its members. The Eagles, the Foresters, the Druids, the Maccabees, the Fraternal Brotherhood, and other orders, including even the women's lodges, furnished free medical service as one of the privileges of membership.

About a year ago the society adopted a resolution pledging the members to do no more lodge practice. This agreement was signed by every physician in Vallejo, both members and non members. The lodges combined and imported a physician from Oakland, to whom was given all lodge work of the place. He made a contract for a year. At the expiration of his contract he left evidently not finding the work either pleasant or profitable. Since that time two other men have been imported to do lodge work. The members of the society however, have with one exception kept their agreement, and have done no lodge work whatever. The member who broke the promise was expelled later. At the last meeting of the society every member expressed himself as thoroughly satisfied with the year's work.

Utah Completes Reorganization.

The Salt Lake County (Utah) Medical Society has adopted the standard constitution and by laws for county societies in full. The *Utah Medical Journal*, in speaking of the matter editorially, says

"This reorganization plan seems eminently proper, in that the physicians are in closer touch than ever before. The responsibility resting on the county societies is greater than before as they, and they alone are made the qualifications of the membership of the

the American Medical Association. Thus the responsibility rests where the applicant is best known. The various schools of practice, so long as the fundamental requirements are the same, are less widely separated than ever before, and, as time goes on, the differences will grow less and less."

"How to Get Legislation."

The *South Carolina Medical Journal* has the following comment, which should be carefully considered by those interested in securing medical and sanitary legislation:

"We all know (or ought to know if we are old enough to be practicing medicine) that legislation is not accomplished in the effulgent sunlight of a noisy public, not on the hustings of a demagogic campaign meeting, nor even (where one might suppose) on the oratorical forum of the house of representatives. It is conceived, laid, and hatched, in political byways and hedges, around the corner, on the dead quiet, with soft words and apt reasoning.

We must appeal to the personnel of the legislature. We must talk to our law makers in person, quietly, sensibly, and without forcibly and with reason. We may remind the legislator that we are striving to protect the public, himself included, from the appalling, if insidious, dangers of quackery and fakery, impress on him that it is not primarily for our good but for his own protection and that of his family that we ask this legislation. Professional aggrandizement plays no part in this appeal. We may point out to him that, as the state officially recognizes and licenses the profession of the state, surely he must agree that the associated members of the profession are best fitted to outline the necessary legislation for the preservation of the public health."

Queries and Minor Notes

ANONYMOUS COMMUNICATIONS will not be noticed. Queries for this column must be accompanied by the writer's name and address, but the request of the writer not to publish name or address will be faithfully observed.

OXYDENDRON ARBOREUM

HENDERSON OKLA., April 5 1907

To the Editor—What is *Oxydendron arboreum* and what are some of its effects and uses? I fail to find reference to it in any thing at hand.

J T MILLS M.D.

ANSWER—This plant is described in the United States Dispensatory Eighteenth edition as *andromeda Oxydendrum arboreum* sour wood or sorrel tree. It grows in the valleys of the Alleghenies from Pennsylvania to Florida. The leaves have a pleasant acid taste and are sometimes used by hunters to allay thirst. While it is used by some as a diuretic in treatment of dropsy, nothing definite is known regarding its properties.

INDUCED HYPEREMIA IN ACNE AND CORNEAL OPACITIES

DULAY CITY MICH. April 8 1907

To the Editor—I have a patient with acne and also one with a corneal opacity. I wish to treat them by the so-called Bler method. Will you tell me how tight a rubber band should be applied to the neck and for what length of time it should be left on.

M B MCCAUSLAND M.D.

ANSWER—According to R. Knapp, an assistant of Bler, a bandage is properly applied when the following conditions obtain. There must be no discomfort felt from the bandage itself nor in the congested region. In the latter there must be simply a feeling of fullness but none of tingling or as if the part were going to sleep. The member should be warm and eventually become warmer than the opposite side and a bluish red color should appear but the pulse must be easily felt. The rule is to apply the bandage for twenty-two hours, then loosen it and allow a pause of two hours after which the bandage is reapplied. Congestion of the head is secured by the use of a cotton rubber band which is 3 cm (1 1/8 in.) wide for adults and 2 cm (4/5 in.) wide for children. The band has a row of eyelets on one side and a hook on the other so that the degree of hyperemia can be regulated by placing the hook in different eyelets. If the band presses on the neck this must be equalized by padding with cotton. Hyperemia induced by suction is a relief by some for the eye and it would seem as if the same method would also be applicable to acne. For a description and figures of some of the suction apparatus see THE JOURNAL June 9 1906 p. 1804.

TREATMENT OF PARACH

CHICAGO April 2 1907

To the Editor—One is struck on reading medical journals with the number of questions asked regarding the treatment of ear

troubles. I would suggest that a formula be introduced in the next Pharmacopoeia for a ready made preparation suitable for the treatment of this condition. As the putting of potent drugs into the auditory canal may be dangerous, the general practitioner is sometimes at a loss to know what to prescribe both as to drug and to quantity. The National Dispensatory still gives the modified *Balsamum tranquillans* of the French Pharmacopoeia but the U. S. Pharmacopoeia has no formula. Of course the busy practitioner will think of oil of thyme, chloroform, tincture of opium, etc., but how about exact quantities? Too little will make the throbbing thumping and buzzing worse whereas too much may cause serious complications.

L. M. YOUNG M.D.

ANSWER—While our correspondent does not indicate what ear troubles he has in view he makes use of some expressions that lead us to suppose he means an ordinary earache, such as the general practitioner frequently meets especially in children. The disease in question under such circumstances is almost invariably an acute otitis media, either catarrhal or purulent in its character. Conditions of this kind have been combated by various remedies. Hot applications on the outside of the ear are usually helpful. Under this heading may be included hot water bags, a covered Japanese hand stove, hot salt or bran bags, and considerable relief is often found from filling the fingers of kid gloves with hot salt and tying up the open ends. These little bags may be laid on a dish placed on the stove until thoroughly heated then applied to the ear canal and covered with a thick cloth. In this way the heated bag comes into close contact with the tissues of the ear canal. The application of steam often gives prompt relief. A tea cup is filled with boiling water a wad of absorbent cotton pressed to the bottom of the cup the water poured out and the cup applied over the ear. Many drugs are found useful in relieving pain and earache. An aural suppository, such as is manufactured by various pharmaceutical houses each suppository containing 1/2 grain of morphin 1 100 grain atropin and 1/2 grain cocaine, is efficacious. These drugs are held together with cocoa butter. They can be gently slipped into the ear and will melt with the heat of the body or their usefulness can be considerably accentuated by the application to the ear of a hot bag. These suppositories seldom fail to relieve earache, provided of course that the ear canal is reasonably clean and free from ear wax, etc. A common prescription is morphin sulphate gr 1/2 atropin sulphate gr 1/8, rose water 3 1/2. Two or three drops of this dropped in the ear will usually give immediate relief. Cocain is sometimes added. Many other combinations might be suggested but most of them would contain one or all of the above ingredients under somewhat varying conditions. These suggestions are based on the supposition that our correspondent refers to acute otitis media with earache.

SYRUPUS ANTISCORBUTICUS

CINCINNATI April 6, 1907

To the Editor—I recently found the term Syrupus Antiscorbuticus. I did not know what it was, and my library failed to enlighten me. I inquired of a number of my friends both medical and pharmaceutical and they also were unable to tell me. Hence I am compelled to appeal to you.

D. S. MCKEE M.D.

ANSWER—This preparation is official in the Swiss Pharmacopoeia and in the French Codex. Hagers' Handbuch der Pharmaceutischer Praxis gives the following composition:

No	Ingredients	Parts	
		Swiss	French
1	Herba cochleariae (common scurvy grass)	100	100
2	Herba nasturtii offic. recentis (water cress)	100	100
3	Radix armoraciae recentis (horseradish root)	100	100
4	Foliorum menthathylis (water shamrock)	20	10
5	Cortex aurantii	25	20
6	Cortex cinnamomi zeylonici	10	5
7	Vinum albi	400	400
8	Alcohol 94 per cent	40	
9	Saccharum	550	500

According to the Swiss Pharmacopoeia the directions for making this are as follows. Ingredients 1 to 8 are macerated for 5 days in a water bath. One hundred parts are distilled off the remainder is percolated and after 6 hours the clear fluid is poured off. It is then boiled down to 350 parts and cooked to a syrup with the sugar. The distillate is then added.

TEST FOR BILE IN URINE

MINNEAPOLIS March 25 1907

To the Editor—Can you give me a reference to a test for bile in the urine in which a color reaction takes place similar to the diazo reaction on the addition of a solution of sulphuric acid hydrochloric acid and sodium nitrite?

H. W. ALLEN M.D.

ANSWER—The test has been described by A. Raphael (*St. Petersburg med. Wochenschr.* abstracted in THE JOURNAL Jan 13 1906).

115 and by Krokiewicz (*Muenchener med Wochschr* abstracted in *THE JOURNAL*, June 9 1906, 1808) Raphael's test consists in using the ordinary diazo reaction. He uses the two solutions commonly employed, viz., solution 1 Sulphanilic acid 5 parts hydrochloric acid 50 parts distilled water 100 parts. Solution 2 Sodium nitrite 0.5 parts distilled water 100 parts. The test for bile pigment can be performed in two ways viz. Either a solution containing 5 c.c. of solutions 1 and 2 or 3 drops of solution 2 is first prepared and mixed with 5 c.c. of the urine to be examined. If bile pigments are present the solution will promptly assume an amethyst color that in a short time turns to cherry red. The red color is quite apparent even in greatly diluted urines or in urines containing only minute quantities of bile pigments. Or the test may be performed by adding 2 or 3 drops of solution 2 to the urine and then 5 c.c. of solution 1. In this case the urine assumes a greenish or yellowish green hue that within 24 hours passes into a cherry red.

The test of Krokiewicz is based on a similar principle but he employs the various substances making up the diazo test reagent in a little different way. He employs, first a 1 per cent solution of sulphanilic acid second, a 1 per cent solution of sodium nitrite third, pure hydrochloric acid. The test is performed as follows. Equal parts of solutions 1 and 2 are mixed. 0.5 c.c. of this mixture is added to 0.5 c.c. of the urine to be examined. If bile pigments are present the mixture of urine and reagent turns red. If now one or two drops of pure hydrochloric acid are added this red color promptly changes to a violet, which remains permanent for a long time. This test is very delicate and can, if necessary, be performed with a few drops of urine or other fluid to be examined for the presence of bile.

The Public Service

Army Changes

Memorandum of changes of stations and duties of medical officers, U S Army week ending April 13 1907

Rockhill, E P asst. surgeon, granted 30 days sick leave of absence.

Boards of medical officers as hereinafter constituted are appointed to meet April 29 1907 at the places designated for the purpose of conducting the preliminary examination of applicants for appointment in the Medical Department of the Army

At Fort Jay, N Y Richard Charles surgeon Shimer I A Whitmore E R. asst. surgeons
At Vancouver Barracks Wash Crosby W D surgeon Flagg, C L E asst. surgeon
At Columbus Barracks, Ohio Raymond, H I surgeon, Ruffner D L Metcalf, R F asst. surgeons
At Fort Monroe Va Carter W T surgeon Ragan, C A Smith L L asst. surgeons
At Jefferson Barracks, Mo Bradley A. D., surgeon Fyles W L Powell W A, asst. surgeons
At Ancon, Canal Zone McCulloch C C. Jr surgeon Lyster T C Crabtree G H asst. surgeons
At Madison Barracks N Y Hallock H M surgeon
At Fort Sheridan, Ill Munson B L surgeon
At General Hospital Washington Barracks D C Howard D C Ashford B K., Higgins J B asst. surgeons.
At Fort Leavenworth Kan Fuller L A Clayton, J B Halloran P S asst. surgeons.
At Fort Porter N Y Hess Louis T asst. surgeon
At Fort Reno Okla Cager B J Jr asst. surgeon
At Fort Ethan Allen Vt Robbins C P asst. surgeon
At Fort Riley Kan Reno W W asst. surgeon.
At Fort D A Russell Wyo Davidson W T asst. surgeon
At Fort Thomas Ky Hathaway L M asst. surgeon
At Fort Rosecrans Cal Huntington P W asst. surgeon
At Fort Snelling Minn Webb W D asst. surgeon
At Fort Logan Colo Lambert S E asst. surgeon

The board will be governed by instructions from the Surgeon General of the Army to whom the reports of the boards will be rendered direct.

Newgarden George J surgeon ordered to report in person to Brigadier General Wm P Hall adjutant general president Army Retiring Board appointed by Paragraph 8 S O 259 War Department Oct. 9 1906 at such time as he may designate for examination by the board. For the purpose of examining Major Newgarden the board will meet at Washington Barracks D C

Usher I M C asst. surgeon granted 10 days leave of absence
Stark Alexander N surgeon granted three months leave of absence to take effect on his being relieved from duty in the Philippines Division and he is authorized to visit China and Japan
Gosman George H R asst. surgeon granted two months leave of absence to take effect after his arrival in the United States and he is authorized to apply for an extension of one month

Howard, D C asst. surgeon granted leave of absence for two months to take effect June 1 1907 with permission to apply for an extension of one month

Wilson W H asst. surgeon will proceed in due season to Fort Porter N Y and report on arrival to the commanding officer for temporary duty as member of a board of officers to meet May 1 1907 for examination of candidates for admission to the U S Military Academy. On completion of this duty he will return to Fort Hamilton N Y

Kilbourne E D asst. surgeon granted 14 days leave of absence

Mabee J I asst. surgeon relieved from duty in the Philippines Division and assigned to duty in the Army transport service with station at San Francisco. Lieut. Mabee will relieve Asst. Surgeon Pinkston as surgeon of the transport *Sherman* on arrival at Manila P I

Pinkston O W asst. surgeon on being relieved from duty as surgeon of the transport *Sherman* by Asst. Surgeon Mabee will report in person to the commanding general Philippines Division for assignment to duty

Bushnell George E surgeon, is detailed to represent the Medical Department of the Army at the meeting of the National Association for the Study and Prevention of Tuberculosis to be held in Washington D C May 6-8 1907. Major Bushnell will repair to Washington in time to attend the meeting of the association and on its adjournment will return to his proper station

Morris E R. surgeon will proceed to Washington Barracks D C and report in person to the commanding officer General Hospital at that post for observation and treatment.

Gregory J C, asst. surgeon relieved from duty in the Army transport service to take effect on completion of his examination for advancement and ordered to Jefferson Barracks Mo for duty

Bosley J R asst. surgeon relieved from duty at Jefferson Barracks Mo and ordered to Fort Casey Washington for duty

Hart J W contract surgeon left Fort Hunt Va. for duty at Target Camp Annapolis Md.

Wall Francis M contract surgeon left Fort Oglethorpe Ga on leave of absence for two months

Hutson T O contract surgeon left Fort Saint Philip La for duty at proper station Fort Moultrie S C

Bell R P contract surgeon left Fort Wadsworth N Y for temporary duty as surgeon of the transport *Kilpatrick*

Woolley Herbert C contract surgeon ordered from New York City to Vancouver Barracks Wash. for duty in the Department of the Columbia.

Larley E W contract surgeon ordered from Sleepy Eye Minn to Vancouver Barracks Wash for duty in the Department of the Columbia

Navy Changes.

Changes in the Medical Corps U S Navy for the week ending April 13 1907

Langhorne C D surgeon detached from duty at the Naval Medical School Hospital and ordered to the Navy Yard Washington D C

Riggs R E P A surgeon detached from the Naval Station Port Royal S C and ordered to the *Texas*

Helmer R G asst. surgeon detached from the Navy Yard Washington D C April 15 and ordered to attend course of instruction at the Naval Medical School Washington D C

Public Health and Marine Hospital Service

List of changes of station and duties of commissioned and non-commissioned officers of the Public Health and Marine-Hospital Service for the seven days ended April 10 1907

Banks C E surgeon granted leave of absence for one month from about April 19 1907

Cobb J O surgeon granted leave of absence for one month or so much thereof as may be necessary on account of sickness

Werthenbaker C P surgeon granted leave of absence for 1 day April 11 1907

Stimson A M asst. surgeon granted leave of absence for 7 days from April 6 1907 under Paragraph 191 of the Service Regulations

Robertson H McG asst. surgeon directed to proceed to Philadelphia for special temporary duty on completion of which to rejoin his station

Salmon T W asst. surgeon granted leave of absence for 1 day March 2 1907 under Paragraph 191 of the Service Regulations

Ward W K asst. surgeon granted leave of absence for 2 days from March 20 1907 under Paragraph 191 of the Service Regulations

Ashford F A asst. surgeon granted leave of absence for 1 day March 2 1907 under Paragraph 191 of the Service Regulations

Frost W H asst. surgeon granted leave of absence for 2 days from March 30 1907 under Paragraph 191 of the Service Regulations

Kastle J H chief of division of chemistry Hygienic Laboratory granted leave of absence for 9 days from April 11 1907

Buonocore F acting asst. surgeon granted leave of absence for 15 days from Jan. 23 1907 on account of sickness

Delgado J M acting asst. surgeon granted leave of absence for 6 days in March 1907 under Paragraph 210 of the Service Regulations

Duke B F acting asst. surgeon granted leave of absence for 3 days from April 10 1907

Crittts T H D acting asst. surgeon granted leave of absence for 21 days from April 12 1907

Kennard K S acting asst. surgeon granted leave of absence for 1 day March 8 1907 under Paragraph 210 of the Service Regulations

Schwartz, Louis Acting asst. surgeon granted leave of absence for 2 days March 3 and 10 1907 under Paragraph 210 of the Service Regulations.

BOARD CONTINUED

A board of medical officers was to meet at New Orleans April 9 1907 for the examination of an alien immigrant. Detail for the Board Surgeon J H White chairman P A Surgeon J L Wilson Acting Asst. Surgeon J T Scott recorder

Health Reports

The following cases of smallpox yellow fever and plague have been reported to the Surgeon General Public Health and Marine Hospital Service during the week ended April 12 1907

SMALLPOX—UNITED STATES

California San Francisco March 24 '07 1 case
Kansas Topeka March 16 '07 2 cases

Massachusetts Lawrence, March 23-30 19 cases
 Minnesota Winona March 23-30 2 cases

Marriages

J FRANK MCGUIRE, M.D., to Mrs Ella M Churchill, both of Alpena, Mich, April 1

BEVERLY RANDOLPH TUCKER, M.D., to Miss Elsie Boyd of Richmond, Va, April 3

PHILIP DONOHOO, M.D., to Miss Anzelett Lowdermilk, both of Joplin, Mo, March 27

OLEANDER HOWTON, M.D., to Miss Edith Olivia Johnson, both of Osceola, Ark, April 17

WILLIAM B McDONALD, M.D., Baltimore, to Miss Maude Arnold at Baltimore, April 3

FRANK EARL BELLINGER, M.D., Council Bluffs, Iowa, to Miss Edna Hunt, at Lexington, Ky, April 6

CLY RUSSELL JONES, M.D. Orlinda Tenn, to Miss Winnie Carter Taylor of Franklin, Ky, March 12

TIMOTHY J FOLEY, M.D Worcester, Mass, to Miss Anna Irene Morris of Roxbury, Boston, recently

OSMER M WILLIS, M.D. to Miss Florence M Gilpin, both of Marietta, Ohio at Parkersburg, W Va, April 2

HERBERT S FAIRALL, M.D., Deer River, Minn, to Miss Edith Callahan of Duluth, at Grand Rapids, Minn, March 22

Deaths

George Rubens Shepherd, M.D. Medical Institution of Yale College, New Haven, 1866 a member of the American Medical Association medical cadet during the Civil War, since 1880 medical director of the Connecticut Mutual Life Insurance Company sometime president of the Hartford City Medical Society, Hartford County Medical Society and Association of Life Insurance Medical Directors lecturer on life insurance medical examinations at Yale Medical School consulting physician to the Hartford Hospital a member of the board of visitors to the Hartford Retreat for the Insane and a member of the advisory board of the *Yale Medical Journal*, at one time a member of the board of school visitors of Hartford an authority on life insurance statistics and a thorough careful and painstaking medical practitioner who was stricken with cerebral hemorrhage in August last, died March 30, at his home in Hartford from pneumonia aged 64 At Dr Shepherd's funeral the honorary pallbearers were members of the various societies with which he was connected The Hartford Medical Society held a special meeting April 3 to take action on the death of Dr Shepherd

Edward Janney Sidwell Lupton, M.D Johns Hopkins Medical School, Baltimore, 1903, a member of the National Association for the Study and Prevention of Tuberculosis and of the Hendersonville (N C) Medical Association, demonstrator of anatomy in George Washington University and interne at Columbia Hospital, Washington, during 1903 and 1904, assistant in the Adirondack Sanitarium, Trudeau, N Y, from November, 1904, to September, 1906, and thereafter a practitioner at Hendersonville, N C, died at the home of his parents near Martinsville, W Va, from pulmonary tuberculosis, March 23, after an illness of two years, aged 20

Ashbel Parmelee Grinnell, M.D. Bellevue Hospital Medical College, New York City, 1869, for many years dean of the Medical Department of the University of Vermont, vice president of the New York Medicolegal Society and an expert in medicolegal practice, a member of the state and county medical societies, died in his apartments in New York City, April 6, from septic endocarditis, following a severe attack of epidemic influenza, aged 61

John Henry Wiggins, M.D. University of Buffalo (N Y), Medical Department, 1879, a member of the state medical society, for several terms president of the Chautauqua County and of the Jamestown Medical societies, one of the incorporators of the Chautauqua School of Nursing, and one of the foremost practitioners of western New York, died at his home in Jamestown, April 1, from nephritis, after a long illness, aged 52

Luman A. Noyes, M.D. University of Pennsylvania, Department of Medicine, Philadelphia, 1862, surgeon of Vermont volunteers and of the Nineteenth Pennsylvania Volunteer Cavalry during the Civil War, thereafter a practitioner of Randolph, Vt, until 1880, when he was appointed post surgeon and later agent at Seal Island in the Behring Sea, died at Chicopee, Mass, January 14, from cirrhosis of the liver, aged 66

James S Corn, M.D. Vanderbilt University, Medical Department, Nashville, Tenn, 1878, a member of the American Medical Association, president of the Howard County (Ark) Medical Society, and one of the most prominent and widely known practitioners of southwestern Arkansas, died suddenly, April 4, in his buggy, from heart disease, five miles from his home in Nashville, aged 56

William J Rush, M.D. Howard University, Medical Department, Washington, D C, 1898, one of the founders of the Potomac Hospital, and a member of the Medico-Chirurgical Society, died at his home in Washington, D C, April 4, from pneumonia, after an illness of one week, aged 35

Simon Peter Graham, M.D. Harvard University Medical School, Boston, 1903, a member of the American Medical Association and a fellow of the Rhode Island Medical Society, visiting physician to St Joseph's Hospital, Providence, R. I, died at his home in that city, Dec 31, 1906, aged 41

John Hotelling, M.D. Albany (N Y) Medical College, 1863, at one time coroner of Schoharie County and for more than forty years a practitioner of Gallupville, N Y, died at his home in that village, March 30 from cerebral hemorrhage, after an illness of six days aged 69

Mason A. Sheffield, M.D. Bellevue Hospital Medical College, New York City, 1864 a veteran of the Civil War, and since 1872 a practitioner of St John N B, and a regent of Mount Allison College in that city died suddenly at his home, March 30, from heart disease, aged 70

Robert T Harrison, M.D. Missouri Medical College, St. Louis 1882 a member of the American Medical Association, and one of the most prominent practitioners of South Central Missouri, died at his home in Dixon, April 4, after an illness of about a year, aged 51

Joseph Augustus Aldrich, M.D. Castleton (Vt) Medical College 1847 acting assistant surgeon, U S Army from Oct 1 1863 to May 1864 when he was on duty during the Indian troubles at New Ulm, Minn, died in New York City, January 4 aged 89

John Presley Fletcher, M.D. Medical Department of the University of New Orleans, 1875, a member of the state and county medical societies, died at his home in Lonoke Ark, March 9 from capillary bronchitis, after an illness of three weeks aged 80

Charles M Willis M.D. Rush Medical College Chicago, 1877 a member of the state and county medical societies, and secretary of the local U S Board of Pension Examining Physicians died at his home in Berlin, Wis, April 1, from neurasthenia aged 57

Samuel V Fitzsimmons, M.D. University of Nebraska, College of Medicine, Lincoln and Omaha, 1901, of Globe, Ariz., a member of the state and county medical societies, died in Miller Valley, near Prescott, Ariz., January 2, from tuberculosis, aged 33

George W Biggers, M.D. Beaumont Hospital Medical College, St Louis, 1889, a member of the American Medical Association, and a pioneer practitioner of Eastern Oregon, died at the home of his son in La Grande, Ore., March 21, aged 71

Dicia Houston Baker, M.D. Laura Memorial Woman's Medical College, Cincinnati, 1898, a member of the American Medical Association, died at her home in Birmingham, Ala., April 4, after an illness of more than two months, aged 44

J G Hardy, L.R.C.S., L.R.C.P. Edinburgh, 1879, one of the best known physicians of the Moose Mountain (Sask.) district and justice of the peace for his district, died at his home in Carlyle, January 14, after an illness of two weeks

Robinson Britton Price, M.D. Faculty of Medicine of Queen's University and Royal College of Physicians and Surgeons, Kingston, Ont., 1866, a practitioner of Lonsdale, Ont., died in Chicago, January 2, from pneumonia, aged 69

Thomas M Woodson, M.D. University of Louisville (Ky.), Medical Department 1860, a practitioner of Gallatin, Tenn., since 1874, died at his home in that city February 12, after a prolonged illness, from paralysis, aged 76

Herman E McMullen, M.D. Western Pennsylvania Medical College, Pittsburg, 1891, a member of the state and county medical societies was found dead in bed at his home in New Castle, Pa., April 6, aged 45

Jahiel C Kilgore, M.D. Rush Medical College, Chicago, 1869 a member of the American Medical Association, died at his home in Monmouth, Ill., April 9, from septicemia, due to an autopsy wound.

Walter Forsythe Finnie, M.D. Cooper Medical College, San Francisco 1885, died recently after a surgical operation, and was buried from the family residence in San Francisco, April 1, aged 49

Thomas E Buck, M.D. Dartmouth Medical School, Hanover, N H., 1860, a member of the state and county medical societies, died at his home in St Louis, April 2, from dropsy, aged 71

David W Garver, M.D. University of Wooster, Medical Department, Cleveland Ohio, 1869, died at his home in West Salem Ohio, from disease of the liver of long standing, aged 60

Dixon Gough, M.D. University of Maryland School of Medicine Baltimore, 1844, died at his home in Baltimore, April 8, from heart disease, after an illness of one month

William N Sullivan, M.D. Cooper Medical College, San Francisco 1892, formerly a surgeon in the Navy, died January 31, at his home in San Francisco, aged 35

Alfred Russell Starr, M.D. College of Physicians and Surgeons in the City of New York 1880, died at his home in New York City, January 11, aged 48

Frederick A Cady, M.D. Michigan College of Medicine and Surgery, Detroit 1896 of Flint, Mich., died Dec 26, 1906, at Waynesboro, Ga., aged 57

Kessuth Coates, M.D. Vanderbilt University, Medical Department, Nashville, Tenn. 1880, died at his home in Wilton, Ark. Dec 11 1906, aged 54

Augustus M Erwin, M.D. Homeopathic Hospital College, Cleveland, 1882, died at his home in Mantau Station, Ohio, February 2 aged 63

Stanley A. DuPaul, M.D. Detroit (Mich.) Medical College, 1883, died at his home in Carleton, Mich., April 7, from lung disease, aged 48

James A. Williams, M.D. Berkshire Medical College, Pittsfield Mass., 1848, of Algansee, Mich., died Dec 20, 1906, aged 56

Remaldo D Clark, M.D. Rush Medical College, Chicago 1875, died at his home in Akron, Iowa, Dec 7, 1906, aged 64

William H Fairfax, M.D. Medical College of Virginia, Richmond, 1858, died at his home in Hague, Va., April 3, aged 72

J H Cain, M.D. Eclectic Medical Institute, Cincinnati 1884, died at his home in Redondo, Cal., January 6, aged 60

Elias W Wood, M.D. Geneva (N Y) Medical College, 1850, died at his home in Oak Park, Ill., April 7

TENNESSEE STATE MEDICAL ASSOCIATION

Seventy fourth Annual Session, held at Nashville, April 9-11, 1907

The President, DR L A YARBROUGH, in the Chair

Officers Elected

The following officers were elected President, Dr A B Cooke, Nashville, vice presidents, Dr R. E Fort, Nashville, Dr Charles P McNabb, Knoxville, Dr R W Tate, Bolivar, secretary Dr Geo H Price, Nashville, reelected, treasurer, Dr W C Bilbro, Murfreesboro, reelected, delegate to American Medical Association, Dr S W Woodyard, Greenville, alternate, Dr C E Ristine, Knoxville

Knoxville was selected as the place for holding the next annual meeting

Management of Occipito Posterior Presentations

DR G C TRAWICK, Nashville, reported three cases and emphasized the fact that such cases require close attention, and that Nature should be depended on, at first, to accomplish delivery, when she has exhausted her forces, the attendant should complete the delivery

DR T J HAPPEL, Trenton, said the general practitioner has these cases to contend with now and then, he should be able to recognize them, so that proper steps may be taken, if possible, to change the position of the fetus from posterior to anterior. If it cannot be done, one should not delay and allow the patient to become exhausted by a protracted labor, hoping Nature will do what she usually often fails to do, but apply forceps promptly

Pseudo Muscular Hypertrophy

DR J R. RATHMELL Chattanooga, reported a case of this affection which was accompanied by chorea. He related two cases which occurred in the same family and two others of which he had knowledge

DR CHARLES P McNABB, Knoxville, said that in 1898-9, he saw a boy with pseudo muscular hypertrophy. A brother of the patient died three or four years previously of the same condition. This child developed chorea, then endocarditis, and two years later he succumbed from the effects of mitral insufficiency

General Anesthesia with Chloroform and Ether

DR HERMAN HAWKINS, Jackson confines himself to these anesthetics for three reasons (1) Because the problem of a perfect general anesthetic is still unsolved (2) Universal use requires general knowledge, and efforts should be made to perfect individual skill in administration by reviewing and emphasizing familiar, but important features of the subject (3) For the sake of brevity. Personally, he prefers ether, but not to the exclusion entirely of chloroform. On the contrary, he urges every physician to be familiar with the administration of both, and to be prepared to say which should be selected in a given case. The anesthetist should be guided by this rule, Give

all needed, but not one drop more than is necessary. Time each administration and measure the amount of drug used in every case.

Needs of a Physician.

DR L. A. YARBROUGH said that the medical embryo should have a normal heritage. He means by this, pure blood circulating through a sound body, nourishing an evenly balanced nervous system, supported by a firm osseous structure, clothed with well rounded muscles, rendered strong by plenty of exercise either in work or athletics. The foundation for his education should be very carefully looked after. He should be taught at home, at the common school, at the high school, the college, and at the university, how to think, how to obtain practical knowledge from books, and how to learn something from everybody and everything with which he comes in contact. If he would become a great scholar he must needs find in study a pleasure, not a drudgery. A taste for study must be cultivated. He needs to have a practical education, in addition to what is commonly called good horse sense, for in learning the theoretical, the practical must not be neglected. He must have a sound body to possess the strength to sustain those qualities which will enable him to surmount all obstacles encountered in the exercise of that art, which is trying to a man's soul, much less his body, and a sound mind to generate the wisdom whence comes the science and the art.

Legislation

DR A. B. COOKE, Nashville, related the experience that he and the other members of his committee had in trying to get certain bills through the state legislature. The committee, however, notwithstanding the bitter opposition encountered from the drug trade, was successful in getting a pure food law passed, for which the association voted its unanimous thanks.

(To be continued)

ST LOUIS MEDICAL SOCIETY

Regular Meeting, held March 23, 1907

The President, DR JOHN C. MORFIT, in the Chair

Re-Education in Organic Lesions of the Cord.

DR MARC RAY HUGHES presented two patients to illustrate his reconstruction of an old method of re education of the motor fibers in sclerosis. Instead of using the stair or step method advocated by Fraenkel, Dr Hughes urges these patients to use their minds to control the muscles all over. The patient is also told to wear rubber heels so as not to be come to familiar with the touch of the floor. The treatment consists more of exercises than anything else, although tonic treatment is also included. These patients simply do what they are told, thus re educating the muscles unconsciously.

Injection of Gasserian Ganglion Through Foramen Ovale for Trifacial Neuralgia

DR V. P. BLAIR employed the method described by Ostwald in one case of trifacial neuralgia with good result. The patient had had an attack of grip about nine years ago, and following this there appeared a tic, mostly of the maxillary division of the fifth nerve although some of the fibers of the second nerve were also involved. The man was never without pain although at times there were remissions in the attacks. There was a good deal of shock after the first injection and the patient complained of a tingling sensation over the root of the nerve but the neuralgia was better. At the end of a week the pain returned, but after the third attempt at injection when the Gasserian ganglion was reached, there was absolute cessation of the pain and a complete anesthesia. There has been no return of the neuralgia since then.

DISCUSSION

DR W. M. C. BRYAN asked whether any untoward effects follow injection of the Gasserian ganglion or of any nerve.

DR LOUIS HAUCK said that in two cases in which he made use of this method of treatment, the first branch of the third

nerve was affected, causing bulging of the eye, strabismus, and a slight ptosis. All these signs disappeared later. Dr Hauck has modified the Ostwald method slightly. He passes the needle along the superior maxillary bone until resistance is met. In order to reach the third branch the needle is passed along the ramus to the pterygoid process, then along the base of the skull until the needle slips from the bone, entering the foramen ovale. He said that even if one should fail to reach it exactly, the injection of the alcohol will not fail to produce the desired results.

CHICAGO MEDICAL SOCIETY

Regular Meeting, held March 20, 1907

The President, DR. GEORGE W. WEBSTER, in the Chair

Relation of Tonsillitis to Rheumatism.

DR E. FLETCHER INGALLS said that he has gradually fallen into error regarding the relation of tonsillitis and rheumatism, and that what has appeared to him merely casual is, in fact, due to an identical cause for the two affections. In from 13 to 29 per cent of all cases of acute tonsillitis. Forty five per cent of the cases of tonsillitis have a rheumatic history, but 16 per cent of other affections of the throat and chest also have a rheumatic history, so that not more than 29 per cent of the cases of acute tonsillitis can fairly be attributed to the rheumatic poisons, and more than half of these are very doubtful. Among his patients only 19 per cent gave a history of previous attacks of articular rheumatism and 18 per cent a history of muscular pains that they ascribed to rheumatism. Eight per cent of the cases of acute tonsillitis were attended by or immediately followed by articular rheumatism, the same number claimed to have had muscular rheumatism, while in 5 per cent the rheumatic attacks immediately preceded the angina. There is not as yet, he said, sufficient evidence to prove that the tonsil is the only or even the chief portal of entrance for the rheumatic poison. Considering, however, that, in all probability, acute articular rheumatism represents a mild type of septic hematogenic infection of the joints, there is no reason why the tonsil with its notorious facility for infection with pyogenic germs should not, possibly, even frequently, assume the rôle of an infected wound leading to septic consequences of a systemic nature. These septic conditions vary in degree and location, and rheumatism is, perhaps, one of the phenomena. The evidence does not justify the belief that inflammation of the tonsil may prevent or take the place of an attack of rheumatism. The statement that the acute beginning of muscular rheumatism is nearly always preceded by tonsillitis is not supported by the histories of his cases, as in only 2 per cent did muscular rheumatism follow tonsillitis. However, in 6 per cent muscular pains that were called rheumatism attended the tonsillitis, though these may have been due to the fever attending the inflammation of the tonsils.

DISCUSSION

DR J. A. CARPIS referred to the type of cases with acute cervical adenitis that occurs especially in children with a simple sore throat. This combination of sore throat and adenitis is important for two reasons. First, the combination has in the last year been more prevalent than usual and, second, an interesting feature is the etiology of these infections. The clinical picture is this. A child has a sore throat, with high temperature and a correspondingly rapid pulse. On examination the throat is not ulcerated, nor is there any follicular tonsillitis but simply a red congested throat. The soft palate, tonsils, pharynx and nasopharynx take part in this redness equally. The temperature remains high for several days. The infection is more severe than one expects from the first examination then gradually the temperature subsides. Perhaps there has been a slight glandular swelling but not pronounced, when the symptoms exacerbate. The temperature rises usually to 104.5°, the pulse is rapid again, the child seems quite as ill or more so than at the first visit and there is noticeable a decided swelling of the cervical glands particularly near the

angle of the jaw, involving the deep cervical glands. The enlargement of the glands, at first discrete, is very apt to become diffuse, and is very rapid in its progress, until the lump becomes the size of a hen's egg or the size of a fist. Usually it is quite hard and tender, irregular in outline, so that the individual glands can not be made out definitely. This tumor mass may remain without much change, the elevation of temperature continuing for a week or two, possibly longer, when it either begins to subside or else the case goes on to suppuration. A red spot appears at some point, and either suppurates spontaneously or is opened, a small quantity of pus being evacuated. Usually the whole group of glands does not suppurate but only a portion of them. He has seen five such cases which would come within this group. Cultures were taken from the throat in four, and in all four influenza bacilli were found in considerable number. There were present also streptococci or staphylococci. Two of the cases went on to suppuration and the pus from both showed streptococci in large numbers.

Dr. D. N. EISENDRATH said that cases of acute enlargement of the lymph nodes of the neck probably correspond to some extent with those described by Pfeiffer in 1899 as glandular fever. In the cases which he saw the enlargement of the lymph nodes was out of proportion to the height of the temperature. A child for instance would have a temperature of 104.5°, with a relatively small number of lymph nodes enlarged not larger, perhaps, than the average-sized marble. During the present winter these cases have assumed a different type in that not only have they affected the lymph nodes of the neck following primary sore throat but they have affected other lymph nodes, as those of the axilla, the groin, apparently taking part in the process of a general infection so that in some cases it was thought there was an acute lymphatic leukemia until the blood was examined. He said there have been reported 11 undoubted cases of primary tuberculosis of the tonsil, the majority of them having been verified by autopsies and by finding primary tuberculosis of the tonsil in which there were no other tubercle bacilli found in the body, the primary focus being in the tonsil, with secondary involvement of the lymph nodes of the neck. A surgeon in operating for tubercular glands of the neck should also remove the tonsils and adenoids. As to the relation between appendicitis and tonsillitis, scarcely a winter has passed during the last two or three years without surgeons having seen tonsillitis in children followed by typical attacks of appendicitis so that clinically the association of the two diseases is quite well established.

Dr. R. H. BADCOCK said that in a very large percentage of cases the portal of entrance of the infection is the tonsil. A large percentage of the cases he sees are instances with some form of heart disease and nearly all which he has investigated have shown either diseased tonsils or a history of previous sore throat. He believes the trend of investigation is to the effect that we must abandon the old notion that acute articular rheumatism is a blood disease in the sense of its being due to some chemical irritant. In fact, it is a specific disease and there have been a great many observations made which go far to prove that the micro organism responsible for attacks of acute articular rheumatism of the classical type is a diplococcus allied to the streptococcus, and which has been called the diplococcus rheumaticus.

With reference to the importance played by follicular tonsillitis in the production of acute endocarditis he cited the instance of a young man in Chicago who developed an acute tonsillitis which subsided apparently in a few days. The patient however did not fully regain his health and later developed symptoms which at first were thought to be those of typhoid fever. The disease proved to be a streptococcus infection with malignant endocarditis pure streptococci having been obtained from the blood. The patient died six months later. The autopsy substantiated the diagnosis which had been made during life. In this case it was clear that infection started in the tonsil that it was apparently a trifling tonsillitis, and yet it resulted in the man's death six months later.

Dr. FRANK S. CHURCHILL said that a child with enlarged and diseased tonsils is constantly exposed to repeated infec-

tions, such as those produced by the streptococcus and influenza bacillus, also the more serious infections, such as those produced by the Klebs-Loeffer bacillus and scarlatina. He always advises removal of adenoids and enlarged tonsils, if possible, in the late spring or summer, on account of the climatic conditions, for he has repeatedly seen children from whom adenoids and tonsils have been removed have persistent colds throughout the winter. The pediatrician does not see an arthritis in the most common and frequent manifestation of rheumatism. He sees, rather, endocarditis. Other manifestations of rheumatism are subcutaneous enlargements, erythema, pleurisy, appendicitis and chorea. Amberg, of Baltimore, who tested the opsonic index of breast fed and bottle-fed babies found that as a rule the index of breast fed babies runs higher than does the index of bottle fed babies showing the greater resistance on the part of such babies to infectious diseases.

Dr. W. L. BALLENGER said that the trend of opinion is that the tonsils are a source of infection not only of tuberculosis but of rheumatism and many other conditions. He has removed many hundreds of tonsils with the capsule intact, and has yet to find many cases in which the crypts did not extend very near to the capsule. In order to remove the atrium of infection in these cases, the tonsils should be removed to the depth of the crypts, and the easiest and most certain way to do that is to remove the tonsil with its capsule.

Dr. C. M. ROBERTSON said there have been more than 11 cases of primary tuberculosis of the tonsil reported up to the present time, but there were only 11 cases found postmortem, because by primary tuberculosis is meant that we are unable to find tuberculosis in other parts of the body than the tonsil as determined by the microscope. He agrees with Dr. Eisenrath that when removing tubercular glands of the neck it is necessary to remove also the tonsils, as the relationship between the two is now established.

Therapeutics

[It is the aim of this department to aid the general practitioner by giving practical prescriptions and methods of treatment for the diseases seen especially in every-day practice. Contributions will be welcomed from our readers.]

Ointments

(Concluded from page 1294)

PHARMACOPŒAL PREPARATIONS

Many good ointments are given in the United States Pharmacopœia, which we can prescribe if we are in doubt as to the proper amounts of the various ingredients used. The following are in the present Pharmacopœia.

Unguentum

Acidi Borici,
Acidi Tannici,
Aque Rosæ,
Belladonnæ,
Chrysarobini,
Diachylon,
Callic,
Hydrargyri,
Hydrargyri Ammoniat,
Hydrargyri Dilutum,
Hydrargyri Nitrat,
Hydrargyri Oxidi Flav.

Unguentum

Hydrargyri Oxidi Rubri,
Iodi,
Iodoformi,
Phenolis,
Pisic Liquidæ,
Potassii Iodidi,
Stramonii,
Sulphuris,
Veratrinæ,
Zinci Oxidi,
Zinci Stearatis.

It might be well at this point to call attention to the fact that all medicines are limited in their action in any pathologic condition, and that the claims made for many of the proprietary ointments are ridiculous. Pharmaceutically they may be elegant, but therapeutically they are not superior to the above list, which nearly covers the ground of treatment as applied by ointments.

CEPATES

It is often desirable to have a firmer base to carry our active principles, especially when a local protective action is also desired. This is accomplished by adding more wax as illustrated by the U. S. P. Ceratum.

Ceræ albæ	3i	30
Petrolatū albi	5v	20
Adipis benzoatī	5iiss	50

Notice that this mixture contains 30 per cent of wax, while the Unguentum contains 20 per cent. Cerates are generally used for local effect alone, as illustrated in the list given in the U S P

Ocratum	Ceratum
Camphoræ,	Resinæ,
Cantharidis,	Resinæ Compositum
Plumbi Subacetatis,	

A convenient use of the terms unguentum and ceratum is in the direction to the druggist, when prescribing a salve, to designate the firmness desired

OTHER MEDIA

In addition to the mineral, vegetable, and animal fats described, there are other media which fulfill the same indications

Oleates—As stated above, olein is a glycerid of oleic acid. If the oleic acid be combined with other substances we have a class called oleates which can be applied alone to the surface of the body or in combination with other fats. The list of oleates on the market is large, but only the following are found in the U S P

Oleatum

Atropinæ	2 per cent of Atropin
Cocainæ	5 per cent. of Cocain
Hydrargyri	25 per cent of Mercury
Quininæ	25 per cent of Quinin
Veratrinæ	2 per cent of Veratrin

The reputed advantage of this class is the rapidity of absorption

Lanolin—Another class is the fat derived from the wool of sheep, which, closely resembling the secretions of the sebaceous glands of man, is readily absorbed. It was put on the market as Lanolin and given in the U S P as Adeps Lanæ without water, and Adeps Lanæ Hydrosus, with about 30 per cent water. Its chemical nature is entirely different from the other fats, it does not decompose and so can carry substances which the others can not, it absorbs an equal quantity of water (adeps lanæ hydrosus) does not contain more than 30 per cent, enabling it to carry many salts in solution.

Cacao Butter—Cacao butter (Oleum Theobromatis) has a field of its own in being used as a vehicle to carry active substances in the form of suppositories to the orifices of the body. It is used also for cosmetic purposes, but seldom in the form of ointments for medicinal purposes.

Glycerin—Glycerin is used in many combinations which are superior to fats for certain cases, mainly in local conditions where fats are not desirable, as follows. Glycerite of starch (Clyceritum Amyli) makes a pleasing base for many purposes. It can be perfumed and made into a very elegant pharmaceutical mixture, as shown by the proprietary articles on the market. The popular clay poultices are mixtures of clay and glycerin with aromatics. The formula is given in the U S P under the title Cataplasma Kaolini.

Another combination of glycerin is Gelatinum Glycerinatum, which is intended to be used as a base for making suppositories, but may be used also for ointments.

Soaps—Soaps are often used as a medium for applying medicinal substances to the skin, but they are generally overrated the beneficial effect being due to the cleansing action of the soap. A moment's consideration will show that a 5 per cent phenol soap will yield a very dilute solution if any amount of water is used.

Terpenes—The essential oils are entirely different from the other oils being formed by the mixture of certain bases called terpenes. Only fifteen terpenes are known while the list of essential oils is very large, the oxidation of these terpenes produces such compounds as camphor, menthol, eucalyptol, thymol, etc. These oils and derivatives are mainly used to perfume pharmaceutical mixtures. A very small quantity is sufficient to change an obnoxious smelling mixture into a very attractive one. The main essential oils may also be used as irritants, antiseptics and anesthetics. The exudations found on trees are usually mixtures of terpenes and a soluble gum. For example, the

exudation of the pine tree yields a solid substance called rosin (Resina) and a liquid turpentine (Oleum Terebinthinæ). The oil is rectified for internal administration and called Oleum Terebinthinæ Rectificatum. The term spirit of turpentine should not be used, as now we use the term spirit, to designate an alcoholic solution of a volatile substance, but we should use the proper name oil of turpentine. Rosin is used on account of its high melting point to harden ointments and cerates. It is present in Ceratum Resinæ, Ceratum Resinæ Compositum and Ceratum Cantharidis. These exudations are the source of many of the balsams which formerly had such a high standing in the treating of all ailments, but now are simply used for the effect that the name produces.

SUMMARY

Ointments are semi solid preparations used for the application of medicinal substances to the surface of the body.

For local effect the mineral fats and the glycerin mixtures should be used as a base.

For systemic effect the vegetable and animal fats should be used. Pharmaceutical skill should be used to make them attractive to the sense of smell by the addition of some perfume and attractive to the eye by the use of some attractive coloring matter and the use of the collapsible tube.

Bronchitis.

If the patient is seen early, while the coryza is still present, the attack may often be aborted by administration of Dover's powder at bedtime, in combination with quinin, as follows

R Pulveris ipecacuanhæ et opii	gr x	65
Quininæ sulphatis	gr v	32

Ft pulvis Sig One such powder at bedtime

The patient may also be given a hot bath or a mustard foot bath, and a glass of hot lemonade, with or without whisky. A saline laxative should be given the next morning. In the case of children a mild calomel purge may be given, followed by castor oil.

The patient should be kept in a warm, moist atmosphere, preferably indoors, and small doses of quinin should be given for a day or two.

Anders states that if this treatment fails, or if the patient does not come under observation early enough, the main objects of treatment should be (a) To render the secretions free, (b) to hasten the expulsion of the sputum after it has been loosened. For this he recommends the following formulas

R Potassii citratis	3vi	24
Liquoris ammonii acetatis	f3v	145
Spiritus ætheris nitrosi	f3i	30
Vini ipecacuanhæ	f3ii	8
Syrupi pruni virginianæ q s ad	f3viii	240

M Sig One tablespoonful in water every two hours until the secretions are loosened.

If the temperature is maintained at 102 or 103 F, or over, tincture of aconite min xxx (20) may be added to the above mixture. If a distressing cough with much tickling of the throat be present codein gr ii iii (0.12 0.19) may be added.

When the above prescription is not productive of free secretion and troublesome cough continues, Anders employs the following combination

R Ammonii chloridi	3v	20
Codeinæ	gr iv vi	25 4
Spiritus juniperi comp	f3ss	15
Misture glycyrrhizæ comp	f3iiss	75
Syrupi pruni virginianæ q s ad	f3iv	120

M Sig One teaspoonful every two hours

Potter, "Materia Medica, Pharmacy and Therapeutics," recommends the following formulas in acute bronchitis

R Antimonii et potassii tartaratis	gr ii	13
Liquoris ammonii acetatis	f3iv	120
Spiritus ætheris nitrosi	f3i	30
Tincturæ aconiti	f3ss	15
Syrupi q s ad	f3vi	180

M Sig One teaspoonful every two or three hours during the first stage

R Fluidextracti cimicifugæ	f3ss	15
Tincturæ opii deodorati	f3i	4
Syrupi toluani q s ad	f3ii	60

M Sig A teaspoonful every four hours

R	Tincturæ sanguinaræ		
	Tincturæ lobeliæ, aa	f3i	4
	Vini ipecacuanhæ	f3ii	8
	Syrupi tolutani q s ad	f3iv	120

M Sig A teaspoonful every three hours

For bronchitis in children Koplik recommends the following simple and practical combination

R	Tincturæ opii camphoratæ	3i	4
	Syrupi ipecacuanhæ	m	2
	Syrupi tolutani	f3ii	60

M Sig One teaspoonful every three hours

In capillary bronchitis in children Potter recommends the following formulas

R	Ammonii iodidi	3i ii	4 8
	Ammonii carbonatis	3ii iii	8 12
	Syrupi glycyrrhizæ		
	Syrupi tolutani, aa	f3ii	60

M Sig A teaspoonful every two or three hours

R	Quinnæ sulphatis	gr vi	4
	Acidi sulphurici dil	m xii	7
	Syrupi	f3ss	15
	Aquæ	f3iiss	75

M Sig A teaspoonful every two hours to a child of 2 or 3 years, older children require more quinin

R	Liquoris ammonii acetatis	f3ss	15
	Syrupi ipecacuanhæ	f3i	4
	Morphinæ sulphatis	gr 1/12	005
	Syrupi acaciæ	f3i	30
	Aquæ	f3iiss	45

M Sig A teaspoonful every two hours for a child 2 years old, when the face is pale, expression languid and skin cool

It must be remembered that expectorants should never be given to infants, as they are unable to cough and may drown in their own secretions, emetics should be prescribed instead. Emetics are necessary when suffocative symptoms become prominent

Burns and Scalds.

In the *Virginia Medical Semi-Monthly* M. Moran recommends the following for the treatment of burns and scalds

Phenol (acidi carbolic)	1 per cent
Balsami peruviani	5 per cent
Olei ricini	94 per cent

Gauze or cotton is saturated with the mixture and applied to the injured part. The dressing should be renewed daily

Alcohol in Affections of Ear, Nose and Throat.

W. L. Ballenger, Chicago, states that alcohol is a valuable remedy for topical applications, and is especially useful in a gargle. It is astringent and antiseptic, and when properly diluted is cooling to an inflamed surface. He recommends the following combination

R	Alcoholis		
	Aquæ cinnamomi aa	f3ii	60
	Liquoris formaldehydi	m ii	12
	Cllycerini	f3v	20
	Aquæ dest. q s ad	f3viii	240

M Sig Use as a gargle

This formula, Ballenger states, makes a good gargle in acute tonsillar and pharyngeal inflammations and in the soreness following removal of the tonsils. In very young children it may be used in a more diluted form

In chronic otorrhea this author recommends alcohol in the following dilutions and mixtures

- 1 Alcohol 1 part, distilled water 2 parts
- 2 Alcohol 1 part, distilled water 1 part
- 3 Alcohol 2 parts, distilled water 1 part
- 4 Alcohol 3 parts, distilled water 1 part
- 5 Alcohol 95 per cent

These dilutions are used principally in the treatment of chronic suppurative otitis media. The meatus is first filled with the weakest solution, then mopped out, and each solution is applied in series until the patient tolerates the 95 per cent solution. If the strongest solution is applied at once it causes considerable pain and irritation, whereas, if the strength is gradually increased these unpleasant results are avoided

Medicolegal

Sale of Medicines by Unlicensed Employés.

The Appellate Term of the Supreme Court of New York holds, in the case of State Board of Pharmacy vs Matthews, that tincture of arnica, tincture of iodine and spirits of camphor are medicines, within the meaning of a law relative to the sale of medicines. That they were not compounded at the counter, but were labeled, sealed and placed on the counter for immediate sale, it does not consider made any difference. It says that the suggestion that the statute, restricting sales of medicines by unlicensed employés, when literally construed, becomes unreasonable and unconstitutional, fails to recognize the ample power of the legislature to enact police regulations for the health and public welfare of the community, which can be threatened in no more perilous way than by the sale of medicines by inexperienced persons

Pharmacopeia Purity Required in Sales by Grocers

The Appellate Term of the Supreme Court of New York says that the defendant in the case of State Board of Pharmacy vs Gasau, a grocer, sold in the course of trade a certain quantity of cream of tartar, which, instead of being 99 per cent. pure, according to the standard of the Pharmacopeia, contained 74.7 per cent of cream of tartar and the rest in alum. Subdivision 2 of Section 197 of Article 11 of the Public Health Law of New York provides that "every proprietor of a wholesale and retail drug store, pharmacy, or other place where drugs, medicines or chemicals are sold, shall be held responsible for the quality and strength" of these commodities, with certain specified exceptions. Section 199 of said article provides that this article shall not apply to the sale by merchants of ammonia, bicarbonate of soda, borax, camphor, castor oil, cream of tartar, "except as herein provided." But the court thinks that the intention of the legislature at the time it enacted the exception contained in Section 199 was obviously merely to except merchants who deal in cream of tartar and certain other persons from the provisions of the article regarding the vital duties of the State Board of Pharmacy and the granting of licenses in pharmacy, and not to except them from the general prohibition against adulteration which had not yet been enacted. When this general prohibitory clause was subsequently enacted, it contained no exception which could shelter the defendant and its unrestricted application was permitted by the express language of Section 199, which was at the same time amended by inserting a qualifying clause that it should operate "except as herein provided." Since the defendant failed to bring himself within Section 199, it followed that he had rendered himself liable for violation of the public health law as a "proprietor of a retail place where chemicals are sold" and consequently the judgment against him must be affirmed

Pay Recoverable for Caring for Smallpox Patients

The Supreme Court of Arkansas says, on the appeal of Marion County vs Bonds and another, where the latter parties sought to recover for waiting on and nursing certain smallpox patients, that the Arkansas statute provides that it shall be lawful for the county to allow accounts incurred by any person in preventing the spread and in nursing and caring for persons in their respective counties who have been afflicted with smallpox. It also provides that "no persons shall be allowed a greater sum for services rendered under the provisions of this act than is customary for such services in other cases." The purpose of the law was to enable county courts to aid in the suppression of smallpox, but at the same time they are prevented by the last clause quoted from making exorbitant allowances for services rendered during the dread and stress of such contagions. They can not allow greater amounts than customary charges for "such services in other cases," i. e., other cases than smallpox. The trial court correctly declared the law in declaring as follows: "That the plaintiffs were entitled to the value of their services according to the market value for such labor in other fever cases—that is, according to

the wages paid for labor generally in like services—and declares that \$5 a day was reasonable wages for the plaintiffs, and declares that they were entitled, under the evidence, to this sum." The plaintiffs made out their cases by proof that the charges made were reasonable for the service they rendered. The proof that they worked night and day, not only nursing the stricken ones, but doing the household work besides, was sufficient to sustain the trial court's finding. The criterion for determining the proper amount is the value of such services, i. e., the service of nursing the sick, doing household duties, etc., made necessary on account of the disease, if such service or similar service were performed in other cases than smallpox. The law makers intended that no unusual and extravagant charge should be allowed on account of the exigencies produced by the dreadful disease. But, in the present cases, even if the amount allowed for nursing, under the proof, would have been unreasonable, the fact that the plaintiffs performed, in addition, customary household duties, made necessary by reason of the contagion, amply sustained the trial court's finding.

Statements Made to Alienist.

The Court of Appeals of New York says that in the homicide case of *People vs. Furlong*, counsel for the defendant claimed that the homicide was committed while the defendant was under the influence of epileptic furor. A physician of great experience in mental diseases testified that he was informed by some one that the court desired him to make an examination of the defendant, and that the latter was brought to the room where the examination was held, and that he made the examination and questioned the defendant to ascertain the truth in regard to his claim of insanity. The examination was made during one of the adjournments of the court, while the defendant was on trial. It was made without the knowledge or presence of either counsel. Whether due courtesy was shown to the counsel engaged in the trial in holding the examination without notifying them, the court says was a question it was not to pass on. The physician testified that before examining the defendant he had said to him that he thought it was for his interest to answer questions unreservedly and truthfully that he might decline to answer any question that he might put to him, and that, while he was examining him in the interests of the court and not as either for or against him, anything he said in answer to his questions might be used against him.

The court holds that the statement which was made to the physician was not within the constitutional prohibition against compelling a defendant to give testimony against himself. The statement made by the defendant was properly received in evidence as an admission or for the purpose of showing that the defendant's statements made at different times were contradictory and inconsistent. The evidence was not incompetent because of the fact that the witness was a physician. The authorities cited by the defendant to show that unsworn statements by the defendant as to transactions prior to the time of the trial can not be given in evidence for use on which to base an expert opinion as to the sanity of the defendant at the time of the commission of the crime all relate to testimony in behalf of the defendant. Such testimony if allowed would permit a defendant to prepare his statement to fit his particular case. The reason for excluding testimony so offered in behalf of the defendant does not apply where it is sought to show conversations and statements of a defendant for use on a trial in behalf of the people.

Prescribing Remedies—Use of Hypnotism or Massage

The Court of General Sessions of Delaware says, in the case of *State vs. Lawson* through Chief Justice Lore charging jury, that the defendant was charged with practicing medicine without a license. Under the statutes of this state it is a misdemeanor for any person to engage in practicing the profession of medicine within the limits of the state without first having obtained a license therefor. The persons classed by the statute as physicians are designated as follows: "Every person (except apothecaries) whose business it is for fee and reward to prescribe remedies or perform surgical operations for the

cure of any bodily disease or ailment, shall be deemed a physician or dentist as the case may be, within the meaning of this act." Revised Code of 1852, amended in 1893, page 58, chapter 7.

The defendant did not contend that he had a license to practice medicine, but relied on the defense that he treated his patients personally by hypnotism and massage, without prescribing any remedies, and that such treatment is not in violation of the statute. The jury's inquiry, then was: Did the defendant, for fee or reward, prescribe remedies or perform surgical operations for the cure of any bodily disease or ailment?

It is the duty of the court to instruct the jury as to the meaning of the word "prescribe" remedies, used in the statute. In medicine, to "prescribe" remedies is defined to be "to write or give medical directions, to indicate remedies." It is not necessary that such prescription should be in writing. It may be given or indicated verbally. Any direction given to the patient for drugs, medicines, or other remedies, for the cure of bodily diseases, directing how they are to be applied to or used by the patient, is a prescription within the meaning of the statute. It would make no difference whether the direction was given by the person in charge of the patient himself or by another person, even though he be a licensed physician engaged by and under the control and direction of the defendant in that particular case. *State vs. Paul*, 56 Neb 309, *Benham vs. State*, 116 Ind 112, *In re Bruendhs' Will*, 102 Wis 45, *O'Neil vs. State* (Tenn.) S W 627.

Personal treatment of one person by another by hypnotism or massage alone, unaccompanied by any direction as to the use of drugs, medicines, or other remedies to be used by the patient, would not come within the term "prescribing remedies" used in the statute. When accompanied, however, by such direction as to the use of drugs, medicines, or other remedies by the patient, it would come within the terms of the statute and be in violation thereof. Should the jury, therefore, be satisfied, from the evidence, beyond a reasonable doubt, that the defendant did, for fee and reward, either by himself or by another under his direction, engage in the business of prescribing remedies for curing bodily diseases or ailments, the verdict should be guilty. If not so satisfied, it should be not guilty.

Proper Evidence in "Traumatic Appendicitis" Case

The Supreme Court of Alabama says, on the appeal of *Birmingham Railway, Light & Power Company vs. Moore*, a personal injury case brought by the latter party, that the plaintiff contended that in a collision of cars, she received a blow on the lower part of the right side of the abdomen which superinduced "traumatic appendicitis." The evidence without conflict showed that she was a healthy woman up to the time of the collision, had never detected or felt any symptoms of appendicitis up to that time, nor had she received any injury before that time. It further showed that she had pain in the region of the appendix from the time she received the blow in her side, on the 11th of June, up to the 22d day of July, at which time she was operated on in a hospital, the operation demonstrating that she had appendicitis. The experts differed in their opinion as to whether the appendicitis, with which she was affected, was the proximate result of the blow—whether it was "traumatic appendicitis." This made a question for the determination of the jury, which rendered a verdict for the plaintiff.

It being necessary for the plaintiff to offer evidence to show that she incurred liability for medical bills, it was proper to ask her to state what was the amount she paid or was to pay the physicians she testified had rendered her medical services. If it was conceded that only reasonable bills for physicians' services were recoverable this did not render the evidence sought objectionable, and, if no evidence was offered to show reasonableness of such services the defendant should have moved the court to exclude the evidence, or should have asked a charge excluding such services as an element of damages.

It was proper to show that all and any means known to medical skill were resorted to in the proper treatment of the plaintiff, to relieve her without subjecting her to the danger of an operation. The court can not say that remedies which

would allay irritation would not postpone the necessity for operating for appendicitis

Notwithstanding that the operation performed on the plaintiff was a successful one, it was competent to show the results that followed the operation, and as one of the results that the plaintiff would necessarily have to be careful with respect to her person, and the length of time such care would have to be observed

Objection was made to the introduction in evidence of a part of a work on "Practice on Surgery," and of another on "Modern Surgery." Each of the books was shown to be a standard medical work. The parts offered in evidence pertained to the pathology of appendicitis, particularly relating to the disputed question of whether or not appendicitis could be caused by a blow or bruise—by traumatism. Under the rule established by this court in 1857 in the case of *Stoudenmeier vs. Williamson*, 29 Ala. 558, the objections to the introduction of the books were properly overruled

- 7 *Present Status of Preliminary Irrectomy as Related to Catarrh Extraction. W. Reber Philadelphia.
- 8 *Unpublished Observations on Endemic Neuritis. J. M. Wheate Boise Idaho.

1 Eruptions in Heart Patients—Schwyzer believes that it is chiefly patients with abdominal arteriosclerosis who are troubled with large amounts of gas. He calls the gastric syndrome in abdominal arteriosclerosis an intermittent claudication of the stomach, the only difference being that it does not show its circulatory insufficiency primarily by the feeling of pain but by a sensation of pressure and by intense and partly futile contractions causing eructations which are followed by total relaxation

3 Spondylosis Rhizomelia.—Gordon reports two cases of this kind. In the first case there was rigidity of the lower part of the spine and a kyphosis at the same level. Symptoms of involvement of the spinal cord and of the roots were very evident. A rheumatic personal or family history was absent. In the second case there were a very marked rigidity of the lower spine and an ankylosis of the large proximal joints of the lower limbs. Pain was present in both extremities and in the back. Cord involvement was evident. There was no rheumatic history. The reflexes in this case were exaggerated, while in the first case they were entirely abolished

7—See abstract in THE JOURNAL, Oct. 6, 1906, page 1130

8 Endemic Neuritis.—According to Wheate, beriberi is an acute infectious disease transmitted by direct infection, probably always through a skin abrasion on some vulnerable portion of the body. The specific organism causing the disease is an exceedingly small bacillus usually seen in pairs, but not encapsulated which is found in the cerebrospinal fluid and blood only during the acute or inflammatory stage of the disease, after which time it rapidly disappears from these tissues. The favorite habitat is virgin soil protected from sunlight. It is a slightly facultative anaerobe, and not very viable being speedily killed by exposure to sunlight as demonstrated by bacteriologic test and by clinical experience. The former classification of the disease as beriberi hydrops and beriberi atrophica is erroneous. There is but one form of beriberi which is characterized by three stages: 1 The stage of invasion. 2 The stage of exudation beginning in the cord and following by toxic motor and sensory paralysis of varying extent, which in typical cases proceeds to 3 the stage of compensation, in which

the disappearance of the bacilli and the toxic stage results in the rapid (usually) disappearance of the dropsy in cases in which softening and dilatation have not progressed to the degree of permanent loss of compensatory action. The degenerative cord and nerve lesion is long present in all moderately severe cases, resembling the lesion in tabes in this particular, and even though the heart lesion appears to have subsided while the patient is leading the inactive life of a convalescent, the damage to function is permanent. This explains the numerous cases of sudden and unaccountable death in patients leaving hospitals apparently cured, as reported by many observers with extensive hospital experience

9—Practically the same paper was published in *Annals of Otolaryngology and Rhinology* for December 1906

10 Harmful Invololution of the Appendix.—Morris draws attention to the fact that the normal involution of the appendix, with replacement of the lymphoid, mucous and submucous coats by connective tissue, may produce unpleasant symptoms for a long period and thus become harmful to the patient. The process is distinctly irritative, not infective. Involution seems to guard the patient against infection. Normal involution of the appendix may begin early in life, but most patients who show its symptoms are over 25 years of age. Symptoms begin gradually, there is autointoxication with its train of symptoms, and there are intestinal dyspepsia, sensation of discomfort in the region of the appendix, an appendix that feels hard and narrow on palpation and hyperesthesia of the lumbar plexus of the nerves. There is persistent distension of the cecum and colon with gas. Irritation of the nerve filaments is communicated to the intimate ganglia of the bowel walls and causes disturbance at the nearest point of the bowel. The sensation of discomfort in the appendiceal region is not due to distension with gas, but to the direct irritation of nerve filaments

11 Cause and Cure of Cancer.—Jacobson advances a new theory as to the cause of cancer. He says that parasites may be concerned in the causation of cancer by means of local irritation that they produce but only thus. The carcinomatous growth, he asserts is a perverted growth, or perverted physiologic growth. At the degenerative period of life, when atrophy of the sexual organs occurs, physiologic energy that is produced in the body finds itself at a loss for an outlet. This energy goes to produce cancerous overgrowths. Peoples with less energy, like the inhabitants of Burmah, Persia and the East, are less apt to have cancer. Coley's results with toxins may depend on the engagement and diversion of this energy. For the etiology of benign growths the author postulates Colnheim's theory, trauma, or parasites producing the irritation. For the etiology of malignant growths a further source is needed—perverted energy. Spontaneous disappearance of cancer would be due to readjustment of the energy of economy. Young healthy individuals can not be inoculated because the fundamental factor, perverted energy is wanting. This accounts for the metamorphoses of benign into malignant growths. Radical extirpation of cancer is not enough because the perverted energy still exists causing recurrence. When cancer occurs in the young it is due to sexual anomalies with maladjustment of energy

12 Eosinophiles.—According to Blumgart the entire disappearance or very marked diminution of the eosinophiles together with a distinct leucopenia goes far to establish the diagnosis of typhoid in doubtful cases. A normal or increased percentage of eosinophiles speaks against typhoid. In cases of undoubted typhoid the presence of eosinophiles, even in small numbers, during the first week is a favorable sign for a probable mild type. Blumgart

patient should be considered cured or dismissed from observation before he has regained permanently at least a normal percentage of the eosinophiles

13 Syphilis.—Mackee advises the exercise of extreme care in making a diagnosis of syphilis in cases unassociated with secondary manifestations before advising the recognized course of constitutional treatment. He says that a careful search for the *Spirocheta pallida* should be made in the primary and secondary lesions of every case, for if this is found it will confirm the diagnosis.

14 Separation of Jointed Twins.—Kieffer relates the history of an African, 66 years old, born on board a slave ship, as one of jointed twins. The mother died after a Cesarean section done by the ship surgeon. The surgeon also separated the twins, of whom, the other died. In the scar over the sternum, at the point of separation, began a keloid, which at the age of eight years, had to be removed, and returned, but not to become thick. Later, other keloids formed, of which one of large size is especially mentioned as appearing over the right temple and parietal region, it has been removed, but has returned, and now shows signs of malignant degeneration.

15—See abstract in THE JOURNAL, March 23, 1907, page 1057.

16 Effect of Industry on Health.—Hanson describes the attempt made recently by the State Board of Health of Massachusetts to establish factory inspection work on a scientific basis.

18 Crusade Against Tuberculosis in Germany.—This is the second installment of Locke's paper on this subject. In it he discusses the care of the sick as well as the prophylactic measures employed, such as the convalescent camps, farm colonies, sanatoria, the special institutions for the far advanced cases, the dwelling house reform, the crusade against tuberculosis in children, and tuberculosis in the army and navy.

19 Pupillary Phenomena in Hysteria.—In the case reported by Putnam, there was dilatation, with complete immobility of the pupil of one eye, associated with spasm of the ciliary muscle of the other eye the pupil of which was rather small habitually, but responded to light and with convergence.

20 Hysterical Trunk Deformity.—Bohm reports a case of lateral curvature of the spine which resisted all attempts at correction, but disappeared under extension or even in recumbency. There was no rotation present. Bohm is convinced that this is a case of hysterical scoliosis.

21 Feigned Eruption.—Following a burn of the right middle finger, White's patient developed a peculiar eruption which involved the back of the right hand and half of the extensor surface of the forearm. There first appeared small red spots which became covered with brown crusts and developed slowly in size until they became as large as a five cent piece. Some of the lesions were two inches in diameter. The patient was well physically, but was extremely nervous. There were also some lesions on the dorsum of the right foot. Over the whole right half of the body the man was anesthetic, even the bulb conjunctiva and nostril being insensitive to severe irritation.

27 Acute Dilatation of Stomach.—Conner bases his study on 82 recorded cases of acute dilatation of the stomach, 2 personal cases and 18 cases of mesenteric obstruction of the duodenum. He considers acute dilatation of the stomach a disease of considerable clinical importance, one which develops under a variety of conditions, but is especially frequent after operation done under general anesthesia. In the majority of cases reported, there was found an associated dilatation of the duodenum, in fact, in a large proportion of cases, about one-half the dilatation is associated with and seems to result from some form of obstruction of the duodenum. The most common cause of such obstruction is found to be constriction of the lower end of the duodenum, between the root of the mesentery and the vertebral column. The constriction occurs when the mesenteric root with the superior mesenteric artery, which runs in it, is stretched tightly across the duodenum as the result of traction exerted by the small intestine hanging over the brim of the pelvis. Although great dilatation of the stomach would doubtless increase the liability to mesenteric obstruction by crowding the intestines into the pelvis, Conner is of the opinion that in some cases at least, the duodenal obstruction is primary. The mortality among the reported cases was 72 per cent, but Conner says that there is much evidence to show that the disease can usually be controlled and cured, if the diagnosis is made and suitable treatment begun before complete collapse of the patient has occurred.

28 Operative Treatment of Fractures.—Vaughan is of the opinion that perfect adjustment in fractures of the long bones is seldom accomplished without operation, except in green stick fractures and in some transverse fractures, in which the fragments may be displaced only partially and have not over ridden as in some cases of Colles' fracture. He favors wire for holding the fragments together, because it is less bulky, because it can be applied with less injury to the soft parts, and because its action in holding the bones together continues longer than any of the other methods in use, except the bone ferrule. He has operated in 102 cases of fracture with only two fatalities, both occurring after operation on the neck of the femur. The methods employed and the results obtained are presented in full.

29 Leukemic Blood in Fracture of Ankle.—In a case of compound fracture of the right ankle, Simon observed a distinct increase in the polynuclear neutrophiles, and a blood picture, which was typical of myeloid leukemia. At the time of the examination the patient was suffering from a cellulitis. The leg was amputated in the lower third and one week afterward, with the recovery of the patient, there was a return to normal conditions.

30 Luys' Urine Separator.—Barringer has employed this instrument with much satisfaction in fourteen cases, two male and twelve female. The histories of nine of these cases are published. He says that any inaccuracy of results obtained by the use of the separator is to be attributed to its employ-

ment in unsuitable cases, or to a failure to recognize traumatic hemorrhage when it occurs. He has found the separator invaluable in cases in which one or both ureteral openings are obscured by cystitis, in cases in which the rapid excretion of pus or blood into the bladder clouds the bladder fluid, and in cases in which in a normal bladder one or both ureteral mouths can not be found.

31 Colloidal Nitrogen in Urine.—The nitrogen which is precipitated by absolute alcohol has been termed by Salkowski colloidal nitrogen. Marriott and Wolf repeated Salkowski's work with 11 specimens of urine, but do not recommend the method for clinical use. In the mixture precipitated from urine by alcohol, the nitrogenous carbohydrate described by Salkowski was not found. The authors state that the colloidal nitrogen of Salkowski does not bear any relation to the undetermined nitrogen.

32 Occult Blood Tests.—Cowie describes his modification of Boas' second modification of Weber's test for occult blood. As small an amount as one milligram of blood is said to produce a distinct reaction with this test. To one gram of stool, softened with water, if necessary, four or five c.c. of glacial acetic acid is added and mixed in a glass mortar. To this mixture, 30 c.c. of ether are added and allowed to extract for several minutes. To one or two c.c. of the extract an equal amount of distilled water is added, and the whole shaken thoroughly. To the resulting mixture, a few granules of powdered, guaiac resin are added, and after this has dissolved there are added 30 drops of old, water white, chemically pure turpentine. By holding the container against the light, or in front of a white surface, the presence of blood is manifested by a distinct light blue color, which develops quickly in the upper half of the mixture, remains for a short time, and gradually disappears. Larger amounts of blood cause a more intense blue.

Cowie conducted several series of experiments for the purpose of determining whether or not the reactions for occult blood occur in the stools of individuals eating a meat diet. He found that individuals eating an ordinary meat diet seldom give a reaction in the stool with the occult blood tests. If a reaction occurs, it is in all probability due to some pathologic process in the gastrointestinal tract. The reader is referred to the original article for the detailed report of Cowie's experiments.

33 Varicose Aneurism of Aorta and Superior Vena Cava.—A case of this kind is reported by Cary. The patient died from rupture of the aorta into the vena cava.

35 Islands of Langerhans in Diabetes Mellitus.—MacCallum reports a case of diabetes mellitus that came to the post mortem room. On examination of the pancreas he found alterations in the islands of Langerhans, but felt that these alterations could hardly be interpreted as degenerative changes nor as changes which might bring about functional insufficiency. On the other hand, there were changes which seemed to indicate an actual increase in the bulk and functional capabilities of these islands. The islands were very conspicuous and seemed larger and much more deeply stained than normal. They were far less sharply outlined than normal and appeared to be almost everywhere directly continuous with the cells of the adjacent acini. In another case, to which reference is made, the pancreas presented an appearance almost precisely similar to that seen by MacCallum.

36 Universal Itching Without Skin Lesion.—In the case reported by Mitchell and Allen the persistent, universal itching was caused by the presence of urobilin in the circulation, which in its turn was the result of a peculiar hemolysis caused by chronic malarial poisoning. The patient also suffered from Raynaud's disease, probably of the same malarial origin, slight renal irritation and general nervousness. All attempts to relieve the itching were ineffectual until treatment was directed to the improvement of the blood making function, together with the employment of sweet baths and stimulating douches, and the moderate long-continued administration of iodids, mercury and arsenic.

37 Fibroid of Vulva.—Schumann reports a case of mucinous fibroma of the left labium majus, occurring in a

woman, 45 years of age, and which had existed for eight years. The tumor was extirpated without difficulty, under ether anesthesia. The hemorrhage was slight and easily controlled.

38 Treatment of Diffuse Suppurative Peritonitis.—As is known, Blake is an advocate of thorough peritoneal lavage in the treatment of diffuse suppurative peritonitis. He says if one has left nothing in the peritoneum that can be absorbed there is no need of drainage. If something is left which probably will not be absorbed, drainage is indicated, but one should drain only to the doubtful substance. The drain is then a sort of safety valve.

In comparing fatal cases, Blake finds that the employment of drainage apparently has had little influence on the results. Of 78 cases of diffuse peritonitis caused by appendicitis, death occurred in 15, 7 of these were not drained and 8 were drained. Of the patients who recovered, 31 were not drained and 32 were drained. Of 13 patients, with peritonitis caused by perforations or ruptures of the stomach and upper intestines, 4 died, 2 of these were drained and 2 were not drained. Of the 9 patients recovering, 5 were drained and 4 were not drained. Of 8 patients with perforation of typhoid ulcers, 4 died, of whom 3 were drained, and one was drained through an abscess in the pelvis. Of the 4 patients who recovered, 2 were not drained, and 2 were drained through the pelvis, there being abscesses present. The abdominal wounds were drained in practically all the cases, the statement "not drained" refers to drainage of the peritoneal cavity. Blake believes that his patients have made smoother recoveries by the omission of drainage, but that careful judgment must be exercised in every case, because some cases need drainage and some do not, some patients seem to do better with irrigation, while some get well without irrigation or drainage, and some patients die, whether drained or not, washed or unwashed.

- 46 Diagnosis and Treatment of Gastric Ulcer. R. H. Halsey. New York.
- 47 Surgical Treatment of Gastric Ulcer. F. Torck. New York.

39 Jaundice.—Three of the five cases reported by Pisani were examples of intralobular compression jaundice, one was a case of interlobular compression jaundice, while the remaining case was a good illustration of extrahepatic jaundice. In all three classes there was an obstruction with escape of bile by the natural channels. From a study of these cases Pisani draws the following conclusions: 1 All forms of jaundice are either intralobular, interlobular or extrahepatic. 2 All forms of jaundice are due to obstruction of the biliary passages. 3 The severity of jaundice in the intralobular and interlobular forms varies, depending on the amount of biliary radicles occluded. 4 The differential diagnosis between the intralobular and interlobular forms of jaundice is generally reached after considering the history of the case and the result obtained in its treatment. 5 In the extrahepatic form of jaundice in which the obstruction is due to biliary calculi it is always advisable to submit the patient to a thorough medical treatment as explained above before allowing him to submit to operative interference. 6 If the obstruction does not yield promptly to medical treatment, surgical interference should be instituted at once.

41 Exophthalmic Goiter.—Horowitz reviews the clinical history of this condition and reports eight cases, seven in women and one in a man. In several of the cases the high frequency current was employed with some success.

43 Nasal and Intranasal Primary Syphilis.—Fanoni reports in detail the histories of four cases of primary nasal syphilis. In one case there was a chancreous erosion of the tip of the nose; in another there was a typical chancre on the right side of the septum of the nose.

a thickened, dull red, semilunar patch on the left ala nasi, and the fourth patient had a thickened incrustation of the inner aspect of the right ala nasi and of all the septum

49 Treatment of Burns and Scalds—An abstract of this article appears in the Therapeutic Department of this issue

51 Treatment of Inoperable Carcinoma.—In the treatment of inoperable carcinomas, Graves employs either caustics, Roentgen, violet or radium rays, or serum therapy. He says that the selection of cases for any particular treatment is of great importance, and calls for considerable judgment and discrimination on the part of the operator. He describes his methods in full, and adds that he would not recommend the use of any of these agents in any case in which the patient is in good condition and will submit to an operation.

52 Retropharyngeal Abscess.—A case of this kind is reported by Glasgow, who emphasizes the importance of careful diagnosis, digital exploration, and the necessity of prompt surgical intervention, as soon as fluctuation can be detected.

62—See abstract in THE JOURNAL, Jan 5 1905 page 72

63 Comminuted Fracture of Both Ends of Radius.—In the case reported by Logan, the chief interest centers in the fracture of the head of the radius although the complication of a Colles fracture of the same bone makes it of greater rarity. The fracture was the result of a fall down a short flight of steps.

64 Foreign Body in Vagina.—Sharpe reports the case of a woman 75 years old who wore a pessary for 35 years. During the last 25 years the appliance had not been removed. The pessary was almost completely enveloped. The vagina had become distorted into an hourglass or funnel shape. The

pessary was very much eroded and opposite the urethra there were slight incrustations.

65 Occlusion of Femoral Vein.—Sheldon reports a case of sarcoma in the left inguinal region, which extended from a point three inches below Poupart's ligament into the pelvis. It seemed to be intimately associated with the femoral vein. There was considerable edema of the leg from occlusion of the femoral vein by pressure. Sheldon succeeded, however, in dissecting the tumor from the leg without wounding it. No hemorrhage occurred, and six months after the operation there is no evidence of recurrence of the tumor, although the entire leg is considerably larger than its fellow. The man has not been prevented from pursuing his occupation as a farmer.

67 Surgery of Typhoid Perforation.—Long presents a brief résumé of the history of this subject and reports two cases. In one case the perforation occurred on the thirtieth day of the disease, and was followed by an extensive peritonitis. An operation was done successfully, but the patient succumbed nine days afterward, from acute dilatation of the stomach. In the second case the perforation occurred through the walls of a Meckel's diverticulum, which sprang from the proximal side of the transverse colon. An operation was done and the patient made a rapid and uninterrupted recovery.

68 Primary Operations for Obstetric Debility.—Reynolds discusses the delivery of debilitated women by operative methods, intrapelvic or abdominal, before labor, in the absence of mechanical impediments and as a method of choice.

69 Small Round-Cell Sarcoma and Lymphosarcoma.—Seelig has made a careful study of the reticulum of these two varieties of sarcoma, with a view to establishing a basis for differentiation. He found that the quantity of reticulum present varies within such broad limits and with such irregularity that it is impossible to associate definitely either type of tumor with the amount of reticulum it contains. He says that inasmuch as a study of the reticulum in lymphosarcoma and in small round cell sarcoma of lymph nodes reveals no histologic differences, it is warranted and expedient to group these two types of lymph node tumors under the one head of malignant lymphomata.

70 Acanthosis Nigricans.—This paper is supplemental to one on cancer of the colon read by Meyer before the May (1906) meeting of the American Surgical Association, and abstracted in THE JOURNAL, June 30, 1906, page 2016.

71—See abstract in THE JOURNAL, Jan 26, 1905, page 351

72 Aid to Intestinal Suture.—The double suspension loop method employed by Jonas is carried out as follows. After the ends of the intestine to be sutured have been smoothly trimmed with scissors, the circumference is divided into three divisions, one of the points of division being at the mesenteric attachment. The intestinal ends are first brought together by a suture at the mesenteric attachments, carefully including the mesentery in the suture, then, at one of three divisions in the intestine, a round, straight, or curved needle, armed with a suture is passed in and out, including the serous and muscular coats in the bite of the needle, leaving a free margin of one-fourth of an inch for inversion. The needle with the same thread is then passed over to the other intestinal end and is made to pierce serosa and muscularis in the same manner as before. The needle is then removed, that part of the thread which extends between the free intestinal ends is then grasped and pulled, thus forming a loop. By grasping the loop thus formed and catching the free ends of the thread, a double loop is formed. A second thread is passed in the same manner as the first one, forming a second double loop. The threads are now grasped with hemostats, and when pulled taut, the intestinal ends are drawn together closely with a sero-serous inversion. The suturing can now be done quickly and accurately by which ever suture method may be deemed advisable.

73 Points in Surgical Technic.—In order to avoid stitch hole infection in cleft palate operations, Vance uses silk worm gut and a pair of ordinary aspirator needles of small size. Through one he threads a silk worm gut double, and through the other a single strand is placed. The needle threaded with the double suture is passed first, the loop being pushed through after the needle, and opposite this is placed the needle

with the single thread. The single suture is engaged in the loop and on withdrawing both needles, the loop pulls the single suture through, leaving it in the proper position to be tied. This procedure is repeated until sufficient sutures are in place. A second point mentioned by Vance is the use of a simple little instrument for removing a silk ligature from a pedicle wherever it may be situated.

- 77 Nature the Good Physician J. D. Macpherson Akron Ohio
- 78 *Obstruction in the Region of the Pylorus T. Jameson Rochester N. Y.
- 79 Visions of Mary Czajka. F. D. Fronczak Buffalo

75 Gastric Ulcer—Smith says that although operative treatment is indicated for frequent and debilitating hemorrhages, and also for repetition of severe hemorrhage, patients suffering from a single severe hemorrhage are best treated medically. Exploratory operations are recommended in obscure cases presenting gastric dyspeptic symptoms and in which gastric ulcer is suspected. Smith says that certain cases of gastric ulcer are favorable ones in which to do resection of the pylorus with anastomosis between the duodenum and stomach.

78 Obstruction in Region of Pylorus—Jameson reports two cases, in one the obstruction was caused by a large gallstone which was lodged at the junction of the cystic and common ducts, and in the other the fundus of the gall bladder adhered to the greater curvature of the stomach in such a way as to cause a bending and narrowing of the pylorus, when the stomach was distended. In a third case there was stricture of the pylorus and in a fourth case a tumor mass was palpable in the region of the pylorus. This patient refused operation and died from starvation after two weeks.

- 84 *Gastric and Pyloric Adhesions A. W. Abbott Minneapolis

80 Mitral Stenosis.—Sears' paper is based on a study of 50 cases which came to autopsy. The cardiac lesion was confined in 25 cases to the mitral valve, in seven others the mitral lesion was the chief finding, but was combined in two with chronic fibrous pericarditis and in five with inflammation of the aortic valves. Aortic stenosis complicated nine other cases, aortic insufficiency three and tricuspid stenosis six. In four of the latter aortic regurgitation was also present and in one case aortic stenosis.

84 Gastric and Pyloric Adhesions—Abbott reports six cases which illustrate the clinical importance of adhesions in the gastric region as a cause of symptoms, the etiology of which is often overlooked. Abbott says that many cases of so-called nervous and hysterical dyspepsia are due to adhesions about the stomach and pylorus, and that in all cases in which an operation is done for ulcer, pyloric obstruction or gall bladder disease, the operation should be considered incomplete unless a thorough exploration for adhesions has been made and those adhesions corrected, so far as possible.

- 4 *Removal of Enlarged Tonsils R. MacLaren
- 5 *Case of Gastroenterostomy Combined with Gastrostomy for Ulceration of the Stomach B. G. A. Moynihan
- 6 *Insanity Its Causes and Increase G. H. Savage

1 Spinal Analgesia—After a very careful study of spinal analgesia in 100 cases, Barker gained the impression that there is undoubtedly a place for spinal analgesia in surgery, but only when those who would employ it have studied its theory and practice fully so far as they are known. He says that it is not for casual use by the inexperienced.

2 Infiltration Anesthesia—Arnold believes firmly in the value of infiltration anesthesia for both major and minor operations. His own list of operations include the following: Gastrostomy, herniotomy, suprapubic cystotomy, closure of an artificial anus, laparotomy for intestinal obstruction, radical cure of varicocele, removal of a mass of suppurating tuberculous glands in the groin, extirpation of the sphenoid vein and its tributaries for varix. Arnold says that by a combination of regional anesthesia of the great nerve trunks, and local infiltration at the seat of operation, major amputations can be performed without general narcosis.

3 Cholelithiasis—Bishop discusses the history of cholelithiasis. He lays great stress on eliciting pain on pressure over the affected bile channel, as a diagnostic symptom.

4 Tonsillectomy—MacLaren prefers to operate with the patient under the influence of a general anesthetic and in the lateral posture. The tonsil is dissected out carefully, traction being made on the gland with a vulsellum forceps, either with a sharp pointed scalpel or with blunt dissectors, depending on the firmness of the gland and the degree of its attachment to

the underlying structure. There is said to be only a moderate amount of bleeding, which is controlled easily by finger pressure. The gland when thus removed has never returned. Healing is generally complete in about ten days.

5 Gastroenterostomy and Gastrostomy—The patient, on whom these operations were performed by Moynihan suffered from extensive ulceration of the stomach and consequent stenosis of the pylorus, the result of the accidental swallowing of hydrochloric acid. A posterior gastroenterostomy was performed in the usual manner, the opening in the stomach being made nearer to the cardiac orifice than usual. The gastrostomy opening was made on the anterior surface midway between the curvatures and well toward the cardiac end. A rubber drainage tube was passed through this opening into the stomach and out again through the gastroenterostomy opening into the distal limb of the jejunum. The patient was fed through this tube for 17 days, when food was again given by the mouth. The tube was removed in the fourth week and the patient has made a complete recovery.

6 Insanity—Savage sums up his paper as follows: Heredity has a small share in the causation of general paralysis, it is more frequently seen in relationship with melancholic than maniacal states. This has some connection with the longer life of persons nowadays. They not infrequently show the weight of years in mental depression. Melancholic states are much more likely to recur in families than maniacal disorders, all forms of insanity, especially sensory hallucinations and their resulting delusions with fixed obsessions, are chiefly dependent on hereditary taint, moral imbecility and asocial and criminal tendencies often arise in very neurotic families. Idiocy, mental weakness and eccentricity are common in the children of physically decadent parents. There is no such thing as transmission of any form of insanity direct, but there is a distinct danger of the passing on of a nervous instability which leads to mental disorder resulting from slight or even normal physiologic strain. Insane parents may have sane children. Consanguinity alone does not produce mental disorder. Eccentric and nervous (not insane) parents may give rise to whole families of idiots or defectives.

- 15 *Case of Strangulated Hernia Associated with Acute Hemorrhagic Pancreatitis. W. H. Brown

7 Permanent Defenses of the Body—Under this heading Abrahams discusses the physiologic reserve or the power which each organ, each tissue, each cell has of calling up its own latent energy in its defense, and the biochemical interrelation of organs, by which one of them can, by chemical means, evoke in another changes which act in its defense, and the nervous mechanism, by which the main organs can call to their aid, not only each other but the nervous system as well.

8 Acute Infective or Toxic Conditions of the Nervous System—In this the second of the Goulstonian lectures, Buzzard takes up the consideration of acute poliomyelitis. He believes that the following conclusions concerning this disease are justifiable:

- 1 It is an acute specific fever occurring sporadically and epidemically, differing from many others but resembling some—variola, for instance—in the facts that its lesions may be discrete or confluent and that its results may be permanent.
- 2 Its essential lesion is an inflammation of the interstitial tissue of the central nervous system due to the presence of micro-organisms or their toxins probably in the blood (but possibly in the lymph) circulating within that system.
- 3 The fact that the gray matter suffers more than the white matter is explained by the greater vascularity of the former and the resistant character of the component parts of the lat-

ter. **4** The same morbid process underlies some cases of encephalitis, both of the brain stem and the cerebrum, among which may probably be included many examples of infantile hemiplegia. **5** The bacteriology is at present practically an unknown quantity. Bacteriologic investigation of the blood, as well as of the cerebrospinal fluid, is indicated, and more complete examination of other organs, especially of the intestines.

9 The Renal Function in Relation to Surgery—In his second Hunterian lecture, Walker discusses the methods at the disposal of the surgeon in estimating the function of one kidney.

10 Carcinoma in Mouse—Bashford and Murray describe certain anatomic and pathologic features of sporadic tumors of the mouse.

13 Test for Acetone in Urine—Jackson-Taylor believes that the sodium nitroprussid test may be rendered more simple, delicate and accurate by substituting strong ammonia for the liquor potassæ and by eliminating the use of acetic acid. The ammonia solution remains on top, and if acetone is present, even in minute quantity, a well marked and absolutely characteristic ring of magenta or petunia appears at the junction of the two fluids, within from one to three minutes, and gradually spreads upward, pervading the whole of the ammonia solution if acetone is present in considerable amount.

14 Rupture of Extrauterine Gestation—In Riddout's case the rupture occurred at about the fourth week of pregnancy. The embryo occupied a position in the region of the isthmus of the left tube. The signs and symptoms presented by the patient pointed to internal hemorrhage of an extensive character.

15 Strangulated Hernia and Acute Pancreatitis—Brown's patient, aged 60, had enjoyed good health up to the time that symptoms of strangulation of a right inguinal hernia manifested themselves. The herniotomy was done, but did not afford the patient much relief from his symptoms. He died the next day, and at the necropsy the disease of the pancreas was discovered. The symptom from which the patient suffered most was vomiting.

17—An abstract of this article will appear in the Therapeutic Department of THE JOURNAL, April 27.

18 Dysmenorrhea—Stevens declares that alcohol should be forbidden and morphia never prescribed for dysmenorrhea. He reviews the treatment usually employed for this condition.

19 Psoriasis—Crocker says that the specifics which experience has shown to be most useful in psoriasis are arsenic, thyroid extract, salicin, and in a few cases, mercurial injections. Locally, tar and chrysarobin may be used. If there is great inflammation, Crocker treats the case as if it were one of eczema.

20 Prevention of Pain After Operations—Clarke says that the three causes of pain after operations are tension, movement and inflammation and that by adopting procedures which will obviate the occurrence of these conditions, no pain will be felt by the patient after operation.

22 Surgical Treatment of Ascites—Bidwell discusses simple tapping and laparotomy. He advises making the preliminary incision through the skin before introducing the trocar so as not to drive into the abdominal cavity any portion of the epidermis, to avoid passing the trocar through the skin.

which is so difficult to sterilize and to insure rapid union of the wound. The edges of the wound are approximated with a horse hair or silk-worm gut suture, and then a dressing is applied and fixed with collodion. In this way prompt healing of the wound is secured.

24 Radical Operation for Inguinal Hernia—Eccles says that the radical operation for inguinal hernia is now well established, has a very low death rate, is very highly successful, and renders a large number of members of the community fit to take their place without the inconvenience and danger of a hernial protrusion.

28 Membranous Dysmenorrhea—Aarons reports four cases of membranous dysmenorrhea with the passage of a cast from the uterus.

30 Empyema of Maxillary Antrum—Dempsey's method of treatment is based on that advocated by Bonninghaus. It is described in full.

34 Pneumococcal Infections Requiring Surgical Treatment—Carmichael discusses the pneumococcal infections of the serous and synovial membranes and of tendons.

35 Therapeutic Notes—Carter discusses briefly the use of trypsin in the treatment of cancer, the use of oil of turpentine in a case of rapidly recurring hemorrhagic effusion into the left pleural cavity, the use of Warburg's tincture (tinctura antiperiodica, N F) in the treatment of cases of malarial fever that resist quinin, and the use of strychnin and arsenic in the treatment of chorea.

39 Diabetes—Monro discusses the clinical history of diabetes and sounds a note of warning in reference to the use of the so-called diabetic bread which, he says, is not always reliable because too often it is loaded with starch. He advises applying the iodine test to make sure that the bread is sufficiently free from starch.

40 Syphilis Simulating Typhoid—Rolleston reports two cases of syphilis that simulated typhoid fever. Typhoid was excluded by a persistently negative Vidal reaction.

49 Campaign Against Malaria in Algeria—Sergent divided the country into zones and has applied prophylactic measures in one zone after another as they were reached in turn in the

course of five years. Comparison of the results in a protected zone and in the unprotected adjacent zone has provided a most striking example of the benefits of the prophylactic measures. The weeds were mown once a month, the suspicious pools of water were petrolized, and oil was sprayed with a garden pump into the recesses of the barns and outhouses followed by spraying with twice the amount of water to kill the adult mosquitoes. The houses were all screened, and adults took 20 cc of quinin one day with 40 cc the next. Illustrated circulars were distributed, containing advice for protection against malaria, and placards with the same were posted in all the cars, depots, postoffices and other gathering places. Large colored posters were placed in the schools, city halls and depots. The picture postal card was also pressed into service to extend the knowledge in regard to transmission of malaria by mosquitoes and the new prophylactic measures based thereon. The conditions in the different zones are tabulated for comparison, the tables giving the "reservoir for the virus" in the inhabitants with enlarged spleens, and stating the possible breeding points for the mosquitoes in the ponds, etc.

50 Experimental Hypersensitiveness to Horse Serum Anaphylaxis—Besredka and Steinhart have been studying the liability to severe and even fatal symptoms noticed when guinea pigs, which have served for dosage of antidiphtheria serum, are injected with horse serum from 10 to 12 days later. Control animals are not affected. The same injection of horse serum made before the end of the 10 or 12 days seems to be harmless for the animal. More than this, it seems to induce the protection of antibodies, which have the effect of vaccinating the animal. The anti-anaphylactic action seems to follow very closely the injection of the horse serum, even a single intraperitoneal injection of 5 cc of horse serum was able to confer immediate immunity, allowing the animal to bear without injury an injection of 0.25 cc of horse serum directly into the brain in less than two hours afterward. This immediate immunity conferred on the brain in less than two hours after intraperitoneal injection, is regarded by the writers as absolutely unprecedented in science. The organs of the animals in which this anti-anaphylaxis had been induced did not display any specific properties when tested later. It seems probable that the sensitized guinea pig, after having served for the dosage of diphtheria serum although it appears healthy, yet in reality has some latent lesion in the brain. Direct injection of the horse serum into the brain arouses this latent lesion to fatal activity. Nicolle reports research on the same subject, especially that phase known as the "phenomenon of Arthus." His conclusions are that it is due to the production of a special and specific antibody in response to repeated injection of horse serum.

51 Hemolytic Test in General Paralysis—Marie and Levaditi have been experimenting with the hemolytic test based on the absence of hemolysis in a sample of blood when the serum to be tested has been added to the fluid. In examination of the cerebrospinal fluid of 17 patients without general paralysis the hemolytic test was invariably negative, while it was positive in 73 per cent of 39 patients with various phases of general paralysis and was constant in the more advanced cases. In nine cases of tabes or tabo paralysis the proportion was only 66 per cent. Their experiences demonstrated further that syphilis alone or a brain lesion alone is not able to induce positive findings. Positive results are observed only when there are syphilitic lesions affecting both cortex and membranes and when these lesions are in an advanced stage. Whether the antibodies in the fluid causing the positive response to the test are really syphilitic antibodies or not can not be decided at present. Experiments on apes are now under way in an endeavor to solve this problem.

54 Experiences with Sleeping Sickness—Throux and Anfreville report seven cases of sleeping sickness among the natives of Senegal. The cases were all imported, the disease not being endemic in this French colony. Martin reports five cases of the disease treated at the Paris Pasteur Institute in white men returning from a sojourn in Africa. Laveran presented their communications and discussed their conclusions, giving also a historical sketch of the various methods of treating sleeping sickness to date. Some of these patients were practically moribund when first seen, but the others are apparently cured. The medication was mostly with arsenic, alone or with strychnin, or a combination of a stain—trypan red—and arsenious acid. The native patient cured is a lad about 13, and Laveran suggests that the disease may be more easily cured in the young than in adults. Four of the white patients have practically recovered, but symptoms recurred and the trypanosomes were found again in the blood when ever the treatment was suspended for any length of time, and there is still auto agglutination of the red corpuscles. Martin gives the arsenic every fifth day at first and then every eighth day, keeping it up for months.

55 Decortication of the Lung for Chronic Empyema—Piquet reports a case of persisting empyema after an extensive stab wound in which three operations with resection of ribs and the Estlander operation had failed to relieve. He then performed the operation advocated by Delorme, which he calls decortication of the lung. Marked improvement followed at once, and in three weeks exercises to strengthen the lung function were commenced. The Roentgen rays reveal the dilatibility of the lung and also the thickness and the resistance of the encapsulating membrane. A pleuro pulmonary process induces the formation of a more adherent membrane than a pleural process alone. The best results are attained with chronic purulent streptococcus and staphylococcus pleuritis. Delorme does not advise decortication of the lung except when the lung remains immovable in spite of respiratory exercises commenced soon after the empyema is incised, especially when the suppurating cavity extends for 6 cm., that is, when the surface of the lung is from 6 to 8 cm. below the wall of the thorax. He cuts a flap including the third and sixth ribs, on the anterior lateral wall of the thorax, the base above at the back. Turning back this flap, he makes the toilet of the pleural cavity and the surface of the lung, and then incises the encapsulating shell that imprisons the lung, taking care not to injure the parenchyma. After mobilizing this shell, he excises it as completely as possible, and the lung at once expands and even protrudes through the opening in the wall of the thorax. The article is illustrated.

57 Treatment of Benign Growths in the Bladder—Weinrich describes three cases which he thinks illustrate the great value and the good results of Nitze's intravesical technic in treatment of papillomata of the bladder. One patient was a physician and he returned three years after the first operation to have it repeated on account of return of the growths. He has since been permanently cured. The first patient has been cured for 10 years to date.

59 Theoretical Study of Bier's Induced Hyperemia—Homberger concludes his article with the statement that with an inflammatory focus outside of the part that is brought red

from the influx of arterial blood, and inside of the region beyond, which is bluish from venous congestion, there is always a zone in which there is hyperemia, and in which oxidating processes are going on with great energy. The blood is unusually rich in carbonic acid, but the waste is rapidly deposited, thus ensuring increased warmth. This venous hyperemia ensures increased oxidation, and this is what is accomplished by Bier with his constricting band. This method does not detract in any way from the value of the old, tried methods of application of cold to inflammation. After the first contraction under the influence of the ice bag, the vessels become widely dilated, including the veins. The cold transforms the arterial hyperemia—in which the oxygen is swept along too rapidly to be utilized—into a venous hyperemia. The latter does not differ in any pathologic-anatomic respect from that induced by Bier's constricting band.

60 Ligation of Thyroid Arteries for Goiter—Enochin gives an illustrated description of six patients with large vascular goiters improved by ligation of the thyroid arteries. This procedure is indicated only in this class of goiter, but it is followed by a progressive reduction in the size of the goiter and subsidence of the subjective disturbances. In some cases the general nutrition is much improved, but the cosmetic result is comparatively slight. In ligating the inferior thyroid artery, he includes the artery and its encircling connective tissue in the ligature, according to Drobnik's technic. A double ligature is not indispensable. A drain between the carotid artery and the spine is liable to cause injury to the vessels.

61 New Method of Anastomosis—Flint has devised a cutting instrument with which he claims it is possible to unite any two hollow organs without soiling the field of operation with the contents of either. It consists of scissors, one blade 16 cm. and the other 25 cm. long, both tapering to a needle point. The walls of the organ to be anastomosed are sutured together. The blades of the scissors are then run through the walls, parallel to the row of sutures, a short distance above them. A second row of sutures is then taken beyond the place where the scissors are run through the walls. After these sutures are drawn up and tied, the walls between the two rows of sutures are cut through with the scissors, bringing the two blades together and then pulling out the scissors entirely. No opening is thus made into either organ until after the two have been firmly united both above and below the opening. He says that in gastroenterostomy and entero-anastomosis on 24 dogs the method has proved its great simplicity, rapidity of execution and the rapid healing of the wound by primary intention. The operation was also done on the intestine of the cadaver, after filling the intestine with water, not a drop of water escaped during the operation. The communication issues from Pallau's Institute for General and Experimental Pathology at Vienna.

63 Surgical Treatment of Non-Cancerous Stomach Affections—Gelpke discusses plastic operations on the pylorus and fixation of the stomach, and asks if they should not be preferred to gastroenterostomy in non-cancerous cases, and if this combination does not deserve wider application. His results with five patients thus treated have been most excellent. One patient was a woman of 53 who had suffered for years from gastric disturbances. The stomach was much enlarged, reaching to the symphysis. A plastic operation on the pylorus plus gastropexy banished all disturbances, and the patient gained 30 pounds in weight and has had no further symptoms during the two years since. In the case of a man of 58 with extreme dilatation of the stomach from cicatricial stenosis, a similar operation restored approximately normal conditions. A woman of 40 with extreme gastropexy and incoercible vomiting has been free from symptoms since the operation was performed. As also a fifth patient, a *capra*, with ulcer symptoms for 22 years. In two other cases a simple plastic operation on the pylorus cured all the disturbances resulting from cicatricial stenosis of the pylorus. In two other cases gastropexy was treated by fixation of the stomach and the results have been permanent for several years to date. The simple operation of gastropexy, he thinks is indicated as much as nephropexy for wandering

kidney, and is less difficult and dangerous than the latter. He had to perform a laparotomy two years afterward on one of his patients for another cause, and found the stomach still solidly fastened in the region of the costal arch. He fastens the middle of the anterior stomach wall, parallel to the greater curvature, to the lower costal arch, passing the needle around the cartilage, or else to the anterior abdominal wall at this level. If convenient, he brings the thread through the entire abdominal wall, using strong silk and taking firm hold. He works through a median incision as the pylorus may require a plastic operation at the same time.

64 Transplantation of Thyroid Tissue into the Spleen.—The picture of an apparently normal little girl accompanies Payr's communication, showing the unmistakable improvement in the child with severe infantile myxedema, whom he treated by implantation of thyroid tissue in the spleen. The operation was done in December, 1905, and his report was mentioned in *THE JOURNAL*, Feb 2, 1907, page 460. The hair nails, manner of holding the head and tongue no longer differ from that observed in normal children, and the child has grown 12 cm in less than nine months, with corresponding improvement in intelligence. The thyroid implanted was taken from the mother.

65 Simplified Operation for Old Chronic Empyema.—Bayer describes a technic which answers the same purpose as Schede's resection of the thorax wall, while it is much less serious as the soft parts are all retained. A vertical incision is made about two fingers' breadths back of the anterior axillary line. It crosses all the ribs at the anterior origin of the serratus magnus, commencing at the third rib and extending to the ninth and tenth. This incision does not injure any large blood vessel or involve any large muscle. Through this incision the ribs are subperiosteally resected for about 2 cm. The entire wall of the thorax is opened with the thermocautery, in the zone thus left without ribs, and, after inspecting the cavity, the ribs were resected to right and left as required. It is astonishing he says how easy it is to shell out the ribs under these conditions, resecting them for as long stretches as deemed desirable with the greatest ease. The operation is further facilitated by a supplementary incision parallel with the lowest rib the first, perpendicular incision crossing it in the middle. If the wall of the thorax is very rigid it may be necessary to scrape the costal pleura and to make a few cross cuts. Only in case of a tuberculous process does he think it necessary to sacrifice the wall of soft parts. He gives illustrations of two patients operated on by this technic. The wall of the thorax does not sink in so far as by the Schede technic while the scars are much less prominent. The retention of all the soft parts reduces the resulting disfigurement to almost nothing.

68 Importance of Bacteriology of Appendicitis.—Halm thinks that important data can be learned from bacteriology which will serve as guides in treatment. If the observations of others confirm his own experience, it will be found that appendicitis due to the streptococcus occurs in an epidemic form in spring and fall, while it is seldom observed at other

seasons. It affects the young especially, and prognosis is good for them, but the rare cases of streptococcus appendicitis in the elderly almost invariably terminate fatally. Streptococcus appendicitis requires immediate intervention, while the comparatively milder colon bacillus appendicitis may heal without intervention. It is possible that the varying statistics of different writers on appendicitis are due to the varying bacteriology of their cases. Halm asserts that in the Scandinavian countries the colon bacillus and the pneumococcus seem to be the general causal agents while in Italy and England the colon bacillus alone is incriminated. In Germany, France and possibly also in America, the streptococcus and the colon bacillus are the germs at work. He has noticed certain symptoms as especially frequent in certain streptococcus epidemics of appendicitis, such as herpes or icterus and thinks that by collecting sufficient data it may be possible to differentiate the severe from the mild cases by the specific symptoms observed and the bacteriologic findings.

69 Illumination of Model Operating Room at Worms.—Heidenhain has four large 1 ampere electric lights suspended from the ceiling to form a rectangle about nine feet above the floor. The operating table stands in the square formed by the lights, and is thus illuminated from all sides. The shadow cast by one lamp is illuminated by the light from the other three lamps. The walls and ceiling are of white tiles, but a dado of dark blue tiles runs around the room to rest the eyes. Kröning insists that with white walls and electric light the eyes must have some place where they can rest and as a protection against being dazzled. The light of a powerful arc lamp outside the operating room enters through an opening in the wall and is focused on a mirror from which it can be reflected into the abdomen or other body cavity by adjusting the mirror.

70 Severe After Effects of Spinal Anesthesia.—Goldmann relates the history of a man of 52 who was operated on under chloroform and morphin for hernia. The operation was tedious, lasting fully two hours, but the patient soon recovered. Two months later he returned for herniotomy on the other side, an insignificant operation for a small reducible hernia. This time the operation was done under spinal anesthesia. The anesthesia persisted for five hours and was followed by severe pains in the feet and calves, back, arms and neck, being most severe in the heels. Large doses of morphin were required to relieve the patient. The pains continued for two weeks. The second day after the operation the heels showed symptoms of gangrene and the skin of the heel became mummified down to the fascia. The patch of gangrene on each heel was about the size of the palm of a hand, and Goldmann ascribes it to a trophic disturbance, the result of the spinal anesthesia. The patches finally healed, but the patient still complains of diffuse pains especially headache, but without objective findings and he presents the aspect of neurasthenia.

76 Operative Treatment of Muscular Torticollis.—Gerdes states that he has obtained most excellent results in 11 cases of wry neck in which he divided the scalenus anticus. This is a comparatively simple operation while the results are fully as good as with more complicated technic and it insures against recurrence better than mere tenotomy. When abnormally shortened the scalenus anticus causes curvature of the vertebrae in the neck. He was unable to find any record of treatment of wry neck by division of this muscle, but he has found that the deformity is corrected when this muscle is severed. He has thus operated on 11 patients since 1897 with excellent and permanent results. He makes a transverse incision about 5 or 6 cm long a finger's breadth above the clavicle beginning over the tendon of the sternal portion. Both tendons are then divided near their origin and also the fascia of the neck until the jugular vein is completely exposed. Then the posterior belly of the omohyoid muscle is drawn upward and outward and the jugular vein is drawn inward. This exposes the scaleni and the phrenic nerve is seen as a white cord running across the scalenus anticus with the brachial plexus over the scalenus medius. The scalenus

anticus is then isolated with a blunt instrument, care being taken to avoid injury to the phrenic nerve, the plexus and the jugular vein, the scalenus anticus is divided over the subclavian artery which lies beneath it. It is easily severed and a distinct snap can be heard. In the depth of the wound the transverse process of the seventh cervical vertebra can be felt. Any existing tendency to cervical scoliosis is at once corrected by the operation. It is not necessary to divide the scalenus medius. He tampons the small incision for forty-eight hours, and after the fourth day commences active and passive exercises, continuing them as required for three or six weeks. He does not approve of supporting apparatus, but trusts exclusively to the early exercises. As division of the scalenus protects better against recurrence than mere tenotomy, while the scar is no more prominent, he advises this technic in all cases of wry neck, even the milder forms.

77 Experimental Study of After-Effects of Spinal Anesthesia—Falkner writes from Chrobak's clinic at Vienna to relate the negative results of a series of researches undertaken on rabbits to determine whether intraspinal injection of an anesthetic, according to the usual technic for spinal anesthesia, would have any permanent effect on the elements of the central nervous system. He reviews the various mishaps that have been reported as occurring in the clinic, but he was unable to detect any changes in the nervous system in the animals for which the anesthetic could have been responsible.

78 Series of Female Monsters from Same Parents—Schürmer relates the history of a healthy married couple, with healthy antecedents who had 8 children. The first three were boys, all robust children, then followed a girl with half of the head wanting, then a robust boy, then another girl with the same deformity, then a strong healthy boy. These seven children were born in the course of fourteen years. An interval of seven years then elapsed, and a third girl was born presenting the same deformity as the others. He thinks that this remarkable series of female monsters confirms the assumption that the sex of the embryo is determined in the ovum and that each sex has its own separate place of development, possibly one ovary for the males and the other for the females. The maternal organism was evidently alone responsible for the monstrosities. In a second case described *in vitro* was delivered of triplets, one small but healthy boy and two girls, both with one half of the head wanting. There was thus a female hemicephalus in five pregnancies of two apparently normal women, mother of a number of healthy sons.

80 Technic of Pubiotomy—Seeligmann urges all who have any experience with pelvis enlarging operations to send him a brief report of each case, to collect material for a decisive judgment in regard to the merits of the different techniques. Address Dr. Ludwig Seeligmann, Hamburg, Germany. The Bumm method seems simplest, but Seeligmann's experience has convinced him that his own technic is the safest. The Bumm technic, he says, has already a record of 5 per cent mortality for the mothers and 5 per cent for the children, not to mention minor mishaps.

80 Ventrofixation.—Liepmann gives an illustrated description of Bumm's method of fastening the uterus to the anterior abdominal wall. Instead of fastening the round ligaments close together, the stitches are taken some distance each side of the incision, and the loop of round ligament is drawn out through a small slit in the peritoneum on each side. By this modification of the original technic the traction of the stitch on each side pulls the top of the fundus of the uterus flat. The fixation is to the submuscular layer of connective tissue, the silk threads being tied over the fascia. The uterus retains approximately normal movability, and the position of the organ and the adnexa is approximately normal.

90 Osteomalacia and the Suprarenals—Bossi here relates the later history of the woman with osteomalacia who improved to such a remarkable extent under suprarenal extract, as mentioned in THE JOURNAL, March 2, 1907, page 817. She was safely delivered of large twins and is now in the best of health, nursing her children. He says that this is almost incredible when he reflects on the serious condition of the woman when first seen, only 23 days before the delivery, when the softened and yielding bones and intense pains suggested imminent danger of their breaking under the stress of the increasing size of the uterus. The favorable outcome he ascribes exclusively to the suprarenal treatment. Another patient with osteomalacia, the pelvis much deformed and yielding to the encroaching uterus in the sixth month of pregnancy, has since been under observation. The woman was scarcely able to stand and could walk only when supported by two persons. The slightest movement, even in bed, caused her intense pain. The pelvis was so deformed from the osteomalacia that the two spinous processes of the ilium were scarcely more than an inch apart. Improvement was manifest almost from the first injection of suprarenal extract, and at date of writing, 12 days later, the patient is entirely free from pain and can walk with merely the help of a cane. Bossi further reports that he removed the right suprarenal gland from a gravid sheep. The animal showed no special disturbances for a week, when it was noticed that it could not step about with the same freedom as before, and in a few hours this interference with the animal's movements became marked. The next day the joints throughout the body showed deformity, the hip bones were evidently twisted inward and were painful on pressure. It now seems to be impossible for the animal to stand up or to walk. Bossi adds that he does not wish to be premature in his judgment, but that this experience certainly denotes some connection between the removal of the suprarenal and the development of the osteomalacia.

94 Human Cells as Parasites—Ribbert presents new arguments to sustain his well known views in regard to the genesis of tumors. He believes that tumors are the proliferation of cells which have lost their connection with the organism as a whole and live on it as parasites. He asserts further that myelogenic leukemia has a similar origin, being nothing but the result of parasitic proliferation of marrow cells which have lost their connection with the bone marrow as a whole. Lymphatic leukemia is the same kind of proliferation in cells of lymphatic organs living on as parasites. Cancer research should aim, he says, to determine what processes of growth gradually separate the cells from the rest of the organism and start them on their parasitic existence.

95 Pathology of the Heart Rhythm—Bönniger describes a number of cases, with tracings, which he classes in a special group for which digitalis must be avoided, as it would only aggravate the condition. The principal feature of the cases is the auriculo ventricular extra systole, which is shown instructively by the Roentgen rays. Other symptoms are extreme irregularity and systolic venous pulse, but the liver does not pulsate. The functional disturbance may be very slight and there are no serious signs of stasis and none of the other signs of tricuspid insufficiency. Systolic active pulsation of the right auricle can be seen with the fluoroscope while the unfavorable influence of digitalis is soon manifest. In a typical case of this kind, a woman of 46, suffering from severe nephritis, presented an irregular pulse with systolic venous pulse, but no symptoms of tricuspid insufficiency. The heart beat was regular but very slow (32), and unmistakably originated in the auriculo ventricular fibers. The bradycardia became transformed later into tachycardia. The venous pulse was then presystolic and very weak. The importance of this simultaneous contraction of the auricle and ventricle is not so much from the standpoint of function, as this may be only slightly impaired, but from the standpoint of therapeutics, as digitalis only aggravates the irregularity and tachycardia. In about 60 cases of venous pulse of which he has the tracings fully a third belong in this group. The tracings closely resemble those of tricuspid insufficiency, but the conditions of the dilatation of the auricle are exactly the reverse from tricuspid insufficiency. The enlargement of the auricle is not due to regurgitation of blood, but the pulsation is an active contraction of the part. He reproduces a number of tracings and compares them with those of Mackenzie.

96 Prognosis of Tuberculosis of the Lungs—Rumpf regards the predisposition or habitus as less important for the prognosis than others assume—other things being equal. More important is the fact of the patient's being a poor eater or having a tendency to catarrhal affections. If these tendencies can be overcome, the outlook seems to be as good for the "predisposed" as for the others. The years between 10 and 30 give the largest proportion of restoration of earning capacity. He percusses with the patient breathing through the mouth and bids him cough while examining each part of the area separately. The character of the râles is particularly important, and whether they are diffuse or limited to a circumscribed area. In his experience, râles vanished in 308 patients under treatment, and 80.6 per cent of these retained their earning faculty into the fourth year afterward. In 356 others, râles could still be distinguished, but they were comparatively slight, and the earning capacity was retained into the fourth year in 89.6 per cent, while in 326 others with metallic râles on dismissal only 12.9 per cent retained their earning capacity into the fourth year, and 75.8 per cent had died. When the pulse is persistently fast, and especially when also small, the prognosis should be guarded as also in cases with unstable pulse and temperature, fluctuating after physical or emotional stress. There is hope that the temperature may return permanently to normal so long as the weight increases or even remains stationary. Climatic factors have been shown to be less important than formerly assumed by the results published from sanatoria in northern countries, Holland, Denmark and elsewhere which compare favorably with those from the most famous sanatoria, summer or winter.

In no other affection does the prognosis depend so much on the character of the patient and his cooperation as in tuberculosis. A much better outcome can be counted on in a sanatorium than when the patient remains in his usual environment, and Rumpf even goes farther than this and separates the sexes, receiving in his pavilion only women patients. He has been much pleased with the improvement that has followed this discrimination, and thinks that it has materially bettered the prognosis for his patients.

97 Differentiating Staining Technic for Tubercle Bacilli—Spengler has found both human and bovine tubercle bacilli in 60 per cent of all his phthisical patients. When this symbiosis is observed the tuberculosis seems to run a more chronic course, while infection with either of the species alone is of a more rapid, progressive type, and such patients nearly always have more or less fever. In order to differentiate the bacilli more readily he has devised three new staining techniques which he describes as adapted for practical clinical use as well as for the bacteriologist. With the first the "Hüllenmethode," the bovine tubercle bacillus shows up gigantic besides the human tubercle bacillus, with other differences. The second technique, the "Pikirmethode" shows and differentiates the bacilli well even when their envelopes have been partly destroyed. The third technique, the "Farblichtmethoden," has particular advantages for all the acid proof bacilli. These techniques succeed, he asserts, when all others fail.

98 New Researches on Dysentery—Kruse brings out among other points that hemorrhagic and diphtheric catarrh of the large intestine can occur solely from toxic influences. Certain conditions may favor the development of virulence in ordinary saprophytes and autoinfection can then result as in pneumonia. The germs thus rendered virulent may infect other individuals and induce typical dysentery in them. Jensen was able to induce dysentery in new born calves by feeding them with boiled milk or giving a small amount of creolin or pyoktanin. The findings in the resulting dysentery were exactly the same as in dysentery under natural conditions. Kruse emphasizes the fact that autoinfection and transmissibility are thus not incompatible. He relates extensive studies on immunization and announces favorable results with an antidysentery serum which unites bactericidal opsonic and antitoxic properties.

100 New Patents—An illustration is given of a little device to put on the finger which automatically holds and compresses the stomach tube so that it can be readily inserted with the finger. Another illustration shows a rest cure shelter that always turns its back to the wind. The rear wall of the little garden house is made of glass to admit the sun shine while keeping out the wind. The whole is built on a kind of turntable and is connected with a large weather vane. As the weather vane shifts with a change in the wind the garden house turns with it always presenting its solid rear wall to the wind.

111 *Neurasthenia as Symptom of Latent Tuberculosis (Neurasthenie und latente Tub.) Weinberg

107 Anomalies in the Thorax Favoring Healing of Tuberculous Lesions in the Lungs—Westenhoeffer reports the post mortem findings in two cases of pulmonary tuberculosis in which the lesions had been arrested and were retrogressing under the influence of compression of the lung from complicating propneumothorax in one case and under the influence of passive hyperemia resulting from a valvular affection in the other. The conditions in the first case resembled those artificially produced by pneumothorax. The second case was curing a tuberculous pulmonary

the conditions resembled those induced by Bier's technic of induced hyperemia. In both cases the spontaneous tendency toward healing occurred as the result of resting the parts, just as a tuberculous affection of the kidneys is benefited by change to a dry, hot climate where the skin perspires so freely that the kidneys are relieved of a large part of their work and are able to heal during this comparative rest. Comparing the two methods of artificial pneumothorax and artificial passive hyperemia, he says that the former accomplishes its purpose of causing the collapse of the lung much more effectually than any other technic yet tried. The valvular affection in his second case had existed for six years, and yet the lesion had not retrogressed to such an extent as in the other case in which the primary lesion had been much more extensive. He concludes from these findings that passive hyperemia is not able to check effectually the development of tuberculous lesions if other unfavorable factors work against it. This assumption is confirmed by a third case in which a primary tuberculous affection developed in the peritoneum notwithstanding existing cirrhosis of the liver. A healthy peritoneum has great resisting powers, but when injured it yields before the mildest invasion. The congestion in the region, resulting from the liver affection, evidently afforded a predisposition to tuberculosis in this case. This was manifest also in another case in which the functions of one lung were impeded by adhesions, the tuberculous lesions in this part being much more severe than in the free parts of the lung. In conclusion, Westenhoeffer declares that hindrance in the performance of its function favors the development of a tuberculous affection in an organ, while complete suspension of function favors a cure.

108 Appendicitis During Pregnancy.—Fellner advocates operating in appendicitis entirely regardless of an existing pregnancy. If the child is dead or if there are appreciable signs of labor, the laparotomy should be preceded by the evacuation of the uterus. If the uterine peritoneum is sound, vaginal Cesarean section may be ventured, otherwise delivery induced by another route is preferable.

111 Neurasthenia as Sign of Latent Tuberculosis.—Weinberg states that it has been a frequent experience in his practice to find that patients exhibiting symptoms of neurasthenia, but without an apparent trace of tuberculosis, developed tuberculosis after a few years. He warns that patients with neurasthenia should be regarded as suspicious of tuberculosis, especially if the complexion is particularly pink and white, or grayish or yellowish or if the patients are very thin. Systematic recording of the temperature or the tuberculin test may reveal the tuberculosis underlying the supposed idiopathic neurasthenia in many cases.

- 112 (XXXIX Internal Medicine No. 3) *Autopsies at Copenhagen (Sektionen am Kommunehospital) V. Scheel.
113 *Comparative Study of Local Action of Anesthetics (Lokal Wirkung von Cocain und Stovain) C. G. Santesson.

112 Autopsies at Copenhagen Hospital and Thymic Death.—A number of the more interesting cases are illustrated among them one of intense lymphosarcomatosis of the stomach and adjoining intestine and another of senile atrophy of the liver with torsion of the gall bladder. A typical specimen of "icing liver" is also shown. In three instances the death of a child could not be explained except by the hyperplasia of the thymus. One was a healthy boy of nearly 11 found dead in bed in the morning with no signs of a struggle apparently sleeping quietly. The thymus measured 2x7x8 cm and weighed 40 gm. Scheel paid particular attention to the size of the thymus in other cadavers to establish the normal size for the various decades in life. In 27 children under six months the thymus ranged in weight from 12 to 19 gm. in 34 children between six months to a year old the thymus ranged from 175 to 21 gm. in 17 between 5 and 10 the thymus weighed from 15 to 233 gm. in 11 between 10 and 20 from 3 to 21 gm. In 64 persons between 20 and 60 the thymus weighed from 16 to 465 gm., the average being about 11 gm. and in 35 persons between 60 and 80, the thymus

ranged in weight from 11 to 384 gm., with an average of about 11 gm. The thymus may induce death by compression on the trachea or on the heart and main arteries, and also by paralysis of the heart by toxic or reflex action. In examining 36 cadavers of persons who had died of delirium tremens, fatty degeneration of the liver and chronic leptomenigitis were the only findings noted with any constancy. Arteriosclerosis was less prevalent than in corresponding groups of non alcoholics of the same age.

113 Local Action of Anesthetics.—Santesson's experiments on frogs and rabbits have demonstrated to his satisfaction that cocaine—and still more, stovain—affect the neurilemma and change it in a specific manner. The myelin and also the neurokeratin are more or less altered, and in some of the nerve fibers were found altogether destroyed. His experiments were made with scraps of nerve just taken from the living animal. His findings indicate a special affinity between the poisons and certain elements of the neurilemma. This affinity favors the penetration of the drug through the protecting sheath to the conducting elements of the nerve.

THE DIGESTION OF THE PROTEIDS OF COW'S MILK IN INFANCY

FRANK X WALLS, M.D.
CHICAGO

The proteids in cow's milk give rise to no digestive or nutritive disturbances in the feeding of young infants. If the foregoing statement be a fact, and I am convinced that it is, then the theories and practices that now hold the American profession with regard to the artificial feeding of infants must be radically altered. For years the idea of proteid indigestibility has existed, based principally on some crude test-tube experiments and the misappreciation of certain appearances of the baby's stools, and this error has lived because none challenged the hypothesis, but everybody accepted the casein indigestion as an easy explanation of the difficult digestion of cow's milk during infancy. However, such a mass of incontrovertible evidence has been presented by Escherich, Heubner and Rubner, Budan, Finkelstein and more especially by Czerny and Keller, that one must now admit that such a thing as the proteid indigestion of cow's milk is untenable.

INDIGESTIBILITY OF PROTEIDS NOT TENABLE

The theories of the difficult digestion of cow's proteid were based on the following hypotheses, as stated by Czerny:

Conclusions drawn from the firm coagulum that forms in a test-tube when rennet is added to cow's milk, and the greater amount of proteid in cow's milk than in human milk, the presence of curds in the stools, mechanical irritation by hard clots, causing colic, etc., the "foreign" albumin of cow's milk, a toxic irritant, and the putrefaction of proteid remnants.

When rennet is added to cow's milk in a test-tube a firm clot forms only when the test-tube is allowed to stand without agitation. If the tube be sealed and slowly inverted so as to imitate, even though crudely, the churning movements of the stomach, a fine flocculent precipitate is formed and if one removes cow's milk from a child's stomach with a stomach tube a similar flocculent precipitate is obtained. If any conclusion can be drawn from the behavior of cow's milk with rennet, it is such as would not speak for its indigestibility. The so-called curds in the bowel movement of infants, by which are meant the common whitish, yellowish-white, or yellowish lumps, are not proteid material, but are fats or fatty soaps, rarely are they inspissated mucus or clumps of bacteria. Chemical examination of these masses will reveal their nature and clinically they can be lessened or caused to disappear from the stools without altering the proteid contents by diminishing or removing the fat from the milk food. In hundreds of experiments in which I have given an undiluted fat-free

milk to babies, at times giving more than a quart in 24 hours, never, after careful examination, have I seen curds in the stools.

For such experiments, distinction must be made between skimmed milk and fat-free milk. Fat-free milk, which can be obtained by the centrifugal separation of milk, contains less than 0.5 per cent. of fat, and such a small amount of fat can be disregarded. When milk is skimmed by allowing it to stand in a suitable vessel until the cream rises and is skimmed away, or even siphoning the lower milk, the amount of fat in such milk is often more than 1 per cent., and such skimmed milk may occasion small, whitish, pin-point masses to appear in the stool when administered to a susceptible infant.

If curds or clots are not formed by the proteids, then no mechanical injury can be produced by the proteids and the symptom of colic has been absent from the babies fed on proteid-rich, fat-free milk.

Biedert's hypothesis of "injurious food remnants," by which he taught that the casein masses precipitated in the stomach were retained in the gastrointestinal tract where they underwent putrefactive decomposition, and irritated the alimentary mucosa and might precipitate an attack of gastroenterocolitis, Biedert's hypothesis can be refuted by experiments with fat-free milk. It is found on experiment that the proteid content of milk resists bacterial decomposition for a long time. In the stools of many infants fed on proteid-rich, fat-free milk I have never been able to discover the least putridity. In three cases of ulcerative colitis I have fed sterilized, undiluted, fat-free milk and have seen the bowel movements quickly change from lumpy, mucopurulent, bloody, putrid evacuations to smooth, salve-like, yellowish-brown movements devoid of offensive odor.

The hypothesis of Hamberger concerning *art-cigenes* and *art-fremdes* albumin has only a theoretic interest. The harmlessness of the proteid can be demonstrated clinically by its administration to any infant. I have given fat-free, proteid-rich milk to a large number of babies, over 200 in hospital and in private practice, to the premature new-born, to the infants in three cases of ulcerative colitis and in three cases of hereditary lues, to many atrophic babies, etc., and the result in each case was the same, so that one can state with the assurance of a mathematical demonstration what must follow every time the experiment is made.

In such an experiment as the following give a baby weighing let us say seven pounds, from three to four ounces of sterilized, fat-free, undiluted cow's milk every four hours, or five feedings in the 24 hours. The child will present no symptoms of distress, no meteorism, no vomiting of clots, no belching of gas, and its bowel movements will be smooth, soft, salve-like, brownish-yellow, homogenous and without offensive odor. The color of the movement may vary from a **very** light **yellow** to brownish-yellow, but with this color every other condition will

described I have made such experiments innumerable times, always with like results. The following cases are reported in more or less detail, illustrating the ease of proteid digestion.

CASE REPORTS

CASE 1 Patient—Baby A. was admitted to Wesley Hospital when three days old with its mother, who had a severe puerperal infection. The infant had a temperature of 100 F. On admission it weighed 5 pounds 12 ounces. Physical examination was negative.

Treatment—The infant was given one half grain of calomel in divided doses

and weak barley water for two days. The temperature was then normal and it was given a small amount of milk, which was slowly increased to three ounces in 24 hours. There were free green curdy bowel movements and the milk was discontinued on the ninth day and one ounce of cream given with whey and barley. The food was continued for three days. The stools were increased in number, the curds became more numerous and the weight diminished. The food was changed, and through an error 20 ounces of whole milk was given for one day, when eight very curdy green bowel movements followed. The following day fat-free milk was given and the character of the stools changed immediately. They were soft and yellowish, with no curds. Two days later a number of fine curds were noted in the stool and it was learned that a siphoned milk, which was not fat free, had been used that day. The babe continued to thrive on the diet as shown in the chart. On September 15 one ounce of whole milk was added to the mixture and on the appearance of small curds it was withdrawn. A week later four ounces of whole milk were added to the food. Next the stools became hard and marble like and whole milk was again withdrawn. Six days after this one ounce of cream was added, after this the bowel movement again became dry and firm and the tongue was coated, then the cream was removed. On the forty-sixth day the child was taken home by the mother in very evident good health, good color, active, eager for its food, no colic, gaining in weight and with clear, saline like yellowish brown stools.

Charts 1 and 2 tabulate the food and progress in this case.

CASE 2 Patient—H., male, aged 3 years, was admitted to Wesley Hospital.

History—There are four children in the family, all well, the father and mother are in good health. The child was breast-fed and had no serious illness until three weeks before admission to hospital, when the present sickness began suddenly

with vomiting, high fever and diarrhea. The fever and diarrhea had continued up to the time of admission. The bowel movements were very frequent, from 10 to 20 a day, were very offensive, liquid and contained blood, mucus and pus.

Examination—The child was in a condition of extreme emaciation and prostration when admitted to the hospital. He weighed 20 pounds. Lying on his back in great apathy, and with deeply sunken eyes, he looked more like a corpse than a living child. He was very dull and exhibited resistance only when disturbed for examination, feeding or changing his diapers. The cervical axillary and inguinal lymph glands were slightly enlarged. The skin was dry and pale, and the tongue

Treatment—Details are shown in Chart 2. The child was placed on stimulation, and fat free milk and arrowroot were ordered every four hours. He took his nourishment only in small amounts and that after persuasion. The following day the stools were examined and found to contain many colon bacilli and cocci, pus, and starch granules. The child vomited several times and rejected his food. On the third day he was fed through a nasal catheter, four ounces of sterilized fat free milk were given six times in the 24 hours. From this time on there was no vomiting and the character of the bowel movements changed. There were never any curds in the stools while he was taking the fat free milk even, as seen in the chart, when he was having more than a quart a day. The soft yellow saive-like stools soon replaced the early stools and putridity was absent. On the fifth day in the hospital his temperature became 102+° F. The following morning the explanation of the rise in temperature was found in a red, swollen and tender condition of the right parotid gland, with this exception the improvement was uninterrupted. The additions that were made to the diet are shown in Chart 3 and illustrate the value of determining the energy quotient, in order properly to nourish the child.

A 10-months-old child, three weeks ago, was taken suddenly ill with ileocolitis. For two weeks the conditions were much like those described in the preceding case. The child was put on fat-free, proteid-rich milk, and is now taking 8 ounces five times a day, or 40 ounces in the 24 hours. The movement was soft, absolutely free from any sign of curd, yellowish in color, saline-like in consistency and inoffensive in odor. The therapeutic result is similar to that in the other cases of ulcerative ileocolitis.

An atrophic child, now in Wesley Hospital, aged 5 months and weighing a half-pound less than he did at birth, that is, 7 pounds, he is taking as food 30 ounces of fat-free, sterilized milk a day. He was admitted to the hospital because his mother was worn out in her efforts to find a food for the child. The baby cried all the time, said the mother. On a fat-free milk, given every four hours, he has gained seven ounces in ten days, has no symptoms of colic and is much more contented. There are never any curds in the stools.

PERCENTAGE SCHEDULES FAULTY

The former ideas of the nutritive and digestive disturbance that arose in the artificial feeding of infants

on cow's milk were based on the hypothesis that the proteid content of cow's milk was difficult to digest and, without demonstrating this, every means were taken to overcome the assumed difficulty. The milk was diluted until the proteids were reduced almost to the vanishing point. The proteids were split by the addition of rennet, and whey containing the "soluble" albumin with cream additions came into popular use. Alkalies, such as bicarbonate of soda or of potash or lime water, were used to diminish the curd coagulum. Cereal decoctions were said to have a similar action. The predigestion of the casein by pepsin or pancreatin was likewise prescribed, and of late we are told that citrate of soda makes proteid digestion easier.

Ludwig F. Meyer says that the difference in the behavior of human and of cow's milk should no longer be sought in the different caseins and their lighter or harder digestibility. The principal difference in the two milks, he says, consists much more in the whey, especially

with regard to the contained ferments and inorganic salts

The fact is we have no single symptom or group of symptoms from which we may conclude that any injury to the infant occurs from the albuminoid material in cow's milk, and with the demonstration of this fact all the methods advocated to aid in the digestion of the proteid are without foundation, are useless and may be harmful. It is not to be understood that this article advocates the feeding of babies on a fat-free or skim-milk diet. The normal baby demands a proportion of fat in its food, and the amount is a problem for individual determination. As mentioned in Dr Brenne-
man's paper, the most frequent source of overfeeding is an excessive amount of fat, and the most dangerous foods are the cream mixtures. The cream mixtures give

too much fat and too little proteid. If, as the champions of the percentage method of feeding tell us, "the modification of the proteid is the most important change necessary in cow's milk, for it is the proteid which gives most of the trouble to the infant's digestion," then it must follow, after the demonstration of the innocuousness of cow's proteid, that the percentage method is built on an erroneous idea. Moreover, since the published schedules on the percentage basis exhibit a high degree of overfeeding and do not accurately tell the amount of food that a child is having, there is little, if any, reason at present for the existence of the method.

THE VALUE OF WHOLE MILK MIXTURES

It may be asked what can be offered in its place, and I should answer the feeding of normal infants on whole milk mixtures, beginning with dilution not to exceed one part of milk to two parts of water and lessening the dilution until whole milk is reached, sometimes from six months to a year, and such whole milk should contain not to exceed from 2 to 3 per cent. of fat rather than 4 per cent., as is present in certified milk.

The baby from the first week should not be fed oftener than every four hours during the day and twice at night, and the amount at each feeding should be enough to satisfy its appetite. Few babies, if fed only every four hours, will take too much food. A check against overfeeding should be applied, however, in every child by estimating the caloric value of the food taken during the 24 hours. The caloric value of the infant's food is a matter of easy calculation.

For a further discussion of the caloric check against overfeeding I refer to the paper by Dr. Brenneman on that subject. It is understood, of course, that the food of the infant should be properly balanced and contain fat, carbohydrates and proteid in due proportion. The food elements, fat, proteid and carbohydrates, are not isodynamic in the sense that metabolism can be properly and continuously provided for on a diet made up entirely of any one or two of these elements. But what this due proportion should be is a matter for study in the individual case and not a part of this paper, except in so far as it points out the harmlessness of cow's milk proteid, and leaves for consideration the importance of a proteid rich diet.

CONCLUSIONS

- 1 There is no evidence that the proteid of cow's milk causes any digestive disturbance in the infant.
- 2 All experiments prove that cow's proteid is easy to digest and resists putrefaction.
- 3 The methods mentioned above as aids in the digestion of the proteids are without reason.
- 4 In sterile, fat-free milk we possess an unequalled therapeutic agent in the treatment of the nutritive disorders of infancy.

Ten Laparotomies for Adhesive Peritonitis with Final Cure—Griffenhagen relates in the *St. Petersburg med. Wochenschr.* for October 13 the details of a case of chronic peritonitis with recurring lesions in a housemaid of 35, a primipara, finally cured after nephropexy had been done four times and laparotomy ten. The woman had had varioloid and scarlet fever as a child, but otherwise nothing could be discovered to account for the adhesive peritonitis. The appendix, adnexa and other organs were sound. The numerous operations were undertaken principally to relieve the intense recurring pains, without much hope of a permanent cure, but the patient has been in good health for eight years since the last operation. The first symp-

GLEANINGS FROM FOUR YEARS' EXPERIENCE IN THE CORRELATION OF CLINICAL AND RADIO-DIAGNOSTIC FINDINGS

C. M. COOPER, M.B.,

Instructor of Medicine, University of California. Director of the
Roentgen Ray Department, Lane Hospital. Adjunct Visiting
Physician, German Hospital. Visiting Physician, City
and County Hospital.
SAN FRANCISCO

During the past four years I have consistently employed as a diagnostic aid the x-ray in the field of internal medicine, and this in hospital, private and consultation work. The method followed was routine, thus: A thorough clinical examination was first made and a tentative diagnosis formed, then a radiogram was taken and, if necessary, the fluoroscope used, if the clinical and radiographic evidences did not tally, the patients were re-examined, special attention being directed to the discrepancy. Thus the clinical and radiographic pictures were finally correlated and the previous errors noted. It frequently happened that many clinicians had the opportunity of seeing the same patient and of forming tentative opinions. Internes, those seeking postgraduate instruction, general practitioners and hospital physicians. In such event the varied errors were recorded.

The first year's work served to develop sufficient skill in the use of the x-ray to make it of service and incidentally to demonstrate the high educational value of the method outlined since

1 Diagnostic errors could be frequently corrected while the patient was under clinical observation.

2 Those who had arrived at wrong clinical conclusions could not readily cavil at the correct one when the latter was based on such correlated and partly visible work.

It seems to me that, notwithstanding the loss of the plates and detailed records in the late San Francisco fire, short reports of group cases showing the diagnostic value of such correlated work and the recording of the lessons learned, and of some of the common mistakes made by internes and those seeking postgraduate instruction, might be of service.

DIAPHRAGMATIC AFFECTIONS

CASE 1—Middle-aged man, whom previous examination had shown to be free from organic disease.

History—An oculist had been testing his eye refraction and had used hyoscin as a pupil dilator. This had upset him, had made him nervous, and that morning he found he could not empty his chest during expiration.

Examination—When he was stripped I was surprised to see that during the expiratory phase two cup-shaped hollows became evident, one at the outer border of each rectus muscle at the lower margin of the thoracic cage. These hollows almost disappeared during the latter part of inspiration, to become again marked during expiration, and the more strenuous the gentleman's expiratory endeavors became, the greater became the capacity of these retractions. The patient was neither dyspneic nor in pain, but was mentally annoyed. The complaint of inability to expire completely, plus the hollows in the line of the diaphragm insertion, naturally suggested some abnormality in the action of that muscle.

X-ray Examination—The fluoroscopic picture was interesting. The diaphragm moved up and down piston like during respiration, but instead of each half being dome-shaped, it was as though the summit of each dome had been cut off, each half presenting a striking resemblance to a table mountain. This appearance was maintained during the whole respiratory phase and was evidently caused by a localized, bilateral spasm of the diaphragmatic fibers.

Since during inspiration the insertion and origin of these

fibers were approximated, the clinical evidence of the spasm diminished during this phase, so that without the fluoroscope I could only have surmised the probable, with the fluoroscope I could see the actual. The fact that such local spasm of this muscle can occur, is instructive and perhaps may be the cause of some of the crampy pains in its neighborhood, though this patient had no pain, and may explain the origin of some of the antero-posterior liver grooves not uncommonly found in the postmortem rooms.

After an afternoon spent on the golf links this man's diaphragm acted in the normal manner. Whether the hyoscin was directly responsible as the man declares, or whether it was simply a factor in producing a nervous condition, during which functional, bilateral local diaphragmatic spasm developed, I cannot say.

The movements of the diaphragm serve as an index of the movements of the basal surface of the lungs, and are better studied with the fluoroscope than in any other way. The edges of the lung base may move in the complementary pleural spaces without there being a corresponding diaphragm movement, and hence diaphragm movement and expansion of the lung basal edges are not necessarily synonymous. The Litten phrenic wave, on the other hand, is caused by the peeling off of the diaphragm from the chest wall in its descent and serves to indicate its excursion. Hence our clinical examination should include a diligent study of both these phenomena.

The most common errors in this connection noted during this work have been

- 1 No estimation of the lung border movement has been attempted.
- 2 The extent of movement of the lung basal edge has been percussed, for only at one or, at most, two spots, and the result has been assumed to answer for the whole margin, consequently the clinical search for localized adhesions or for small loculated basal effusions, was insufficient, and any deductions drawn as to their presence or absence were illogically based.
- 3 The pulling up of the chest wall was commonly percussed as diaphragmatic movement.
- 4 No phrenic wave was looked for.
- 5 If looked for, the inspiratory sucking in of the lower intercostal spaces was often mistaken for it.
- 6 Those who looked for and found it, often considered it unnecessary to estimate by percussion the lung border movement in a circumferential manner, even though they had only seen the phrenic wave in the axillary region.
- 7 Palpation sensitiveness was rarely sought for.

Practical clinical skill in the diagnosis of conditions in this region is difficult to acquire. The fluoroscope will aid much in the interpretation and, if used correctly, in the acquisition of such clinical ability.

OLD APICAL DISEASE

CASE 2—A young, well-developed woman, came to my office desiring to know the nature of a lump in her neck. There was a history of chronic cold some years previously.

Examination.—Inspection, palpation, percussion, and auscultation revealed nothing abnormal, except that the right supraclavicular and infraclavicular regions were not as prominent as the left.

X-ray Examination.—The fluoroscope showed a pear shaped, dark, clean edged shadow almost as large as an English walnut, just under the right clavicle. The history of a cold, the slightly sunken apex, the dense shadow, indicated an old, healed and probably calcified tubercular focus. The glands in the neck were considered tubercular and their removal advised, the patient being told of the old lung lesion. She visited many physicians, all of whom denied that there was or had been anything wrong with the right lung. She returned to tell me of my error, and it was only when she saw the dense shadow on a radiograph plate that she recognized the truth of my contention.

This case forms one of a series of similar ones in

which in well-developed persons a slightly shrunken apex was the clinical corollary of a marked, clean-cut radiographic shadow. Such old lesions are often not noted in clinical work, since such patients present no symptoms of active lung disease.

The following errors are common

- 1 Very little time is given to inspection and hence slight retractions are not noted.
- 2 The height and breadth of the lung apices are not as a routine measure percussed.
- 3 If differences in height and breadth be noted, they are not infrequently interpreted as errors of development.

Patients with such old lesions react to tuberculin, they occasionally get influenzal apical infiltrations. The composite picture almost invariably insures a diagnosis of active tuberculosis, even though no tubercle bacilli can be found, and, while this is satisfactory from the standpoint of treatment, a report of the cure of such cases of supposedly active tuberculosis is, of course, very misleading. The radiograms themselves may aid in the deception, but the continuous absence of the tubercle bacilli, the presence of bacillus of influenza, and the much darker, old shadow in the radiogram will, when correlated, serve to lead us to a correct diagnosis.

Of the relative value of pure clinical and radiographic work in the diagnosis of incipient apical tuberculosis I will say nothing, inasmuch as these methods are no more rival measures than are the clinical examinations of an acute abdominal lesion and the estimation of that patient's leucocyte count, but are handmaidens to each other. This case brings out the value of the radiogram from the standpoint of the relationship between the physician and the patient. The doubters become convinced when a radiogram of the normal and a radiogram of their own diseased lung or enlarged heart is shown them and become much more amenable to treatment and ready to diligently carry out the physician's instructions.

CENTRAL PNEUMONIC PATCHES

CASE 3—Patient, male, lately come to San Francisco from China, was seen in consultation. He complained of daily chills and excessive sweating.

Examination.—Patient looked septic. Liver and spleen much enlarged. Leucocytes 12,000. The heart and lungs seemed normal, the abdomen was not rigid, the liver was not tender, no malarial parasites could be found in the blood, and no amebæ in the stools, the urine was normal. He had been taking quinin with no apparent effect. We were inclined to suspect the presence of a deep seated liver abscess, but before deciding, we determined to make a fluoroscopic examination.

X-ray Examination.—With the fluoroscope we saw, centrally placed in the left lower lobe, just above the diaphragm, a dense shadow about the size of a tangerine orange. At deep inspiration the diaphragm descended and allowed the light to penetrate between it and the mass.

Re examination.—Carefully re-examining the patient and paying particular attention to the left posterior lung base, one could detect over the site of this shadow, an increased resistance on percussing with the passive finger resting firmly on the chest, and over this area the vocal fremitus was diminished and the breath sounds faint. These physical signs alone would not have justified a diagnosis, and at best would have suggested waiting to determine if they should change. The correlated picture, however, made the diagnosis of a central patch of pneumonia, with a blocking of its feeding bronchus, occurring in a man who previously had a large liver and spleen (probably hypertrophic stage of atrophic cirrhosis) extremely probable and such the after history proved the case to be.

CASE 4—A young Englishman, who had come from China was seen in consultation with Dr. Brunn. He had been having chills and fever, and marked sweating, for which he had been unsuccessfully treated with quinin.

Examination—No parasites were found in his blood, his leucocyte count was 12,000, no amebæ present in the stools. Liver and spleen both enlarged. The tentative diagnosis here also had been liver abscess. Examination of the lungs disclosed an area, just below the left scapular angle, where there was an increased percussion resistance, here a few râles could be heard and the expiration was slightly bronchial. A diagnosis of a central patch of pneumonia was made and its presence afterward confirmed by the fluoroscope. The malarial parasites were later found so that we had to do with a case of malaria, which a central patch of pneumonia had complicated.

These two cases were interesting from several standpoints. In the first place, they show us we must not jump at a diagnosis of liver abscess in patients who have come from districts in which such abscesses are not uncommon, even though the past history, the symptoms and signs (chills, fever, leucocytosis, big liver) and the apparent absence of other causes are suggestive. The first case illustrated the value of the ray in the diagnosis of patches of central pneumonia which present few signs, and such silent pneumonic areas are not rare particularly in children. Further, it convinced me that I was better able to recognize such deep-seated infiltration by the sense of resistance than by the percussion note. This has been repeatedly impressed on me in this work, and in the clinics, where I try to get the men to test their results obtained from percussion sound and percussion resistance, I find they come to realize the highest value of the latter. The same applies to the determination of the heart borders and of superficial and deep dulnesses generally. Personally I know that if I wish to obtain percussion results corresponding with x-ray findings I have to go systematically over the chest, with light percussion, with moderately heavy percussion, with percussion resistance, the passive finger resting lightly on the chest wall, and with percussion resistance, the passive finger resting firmly on the chest wall.

I believe that in neglecting to emphasize the value of percussion resistance many teachers and authors err. Perhaps some physicians are so gifted in tone perception, etc., as to render other methods superfluous, but in those whom I have tested the pressure sense has become more reliable.

PERIBRONCHIAL GLANDULAR ENLARGEMENTS

CASE 5—A young woman, seen in consultation with Dr. Wilson Shiels, had lost much weight. Dr. Shiels was unable to fatten her by any method whatever. No other symptoms were present except a slight cough.

Examination—No cause was revealed for this loss of weight. A few glands could be felt in the iliac fossæ, and there was, perhaps, a slight percussion palpation resistance over each lung root. The other signs, supposedly characteristic of the presence of peribronchial glands, were absent. Nevertheless the probable diagnosis seemed to me peribronchial tuberculosis.

X-ray Examination—We took a plate in order to determine this and found a good deal of infiltration around each lung root. At one spot a tubercular area had become calcified; the rest of the lung was entirely clear and the diaphragm at its normal level.

This case is a type of several I have seen in which clinically there have not been sufficient signs to render the diagnosis of peribronchial glandular tuberculosis more than probable. On the other hand, indications were absent of involvement of the more readily examinable structures in a person who looks tubercular and behaves clinically as if tubercular. In many such patients (both adults and children) I have by means of the radiogram demonstrated the presence of peribronchial glandular enlargement. One can not from one plate conclude that the process is still an active one. To

determine this another plate taken under the same conditions must show an increase in the area of infiltration, or combined with the picture we must have the clinical indications of tuberculosis, such as evening rise of temperature, cough and, of course, at some time or other tubercle bacilli in the sputum.

Occasionally one sees patients in whom quite an extension has taken place from the root into the lung toward the tip of the shoulder, this central infiltration exhibiting exceedingly few indications of its presence, but the radiogram readily reveals the extensive involvement. We must, however, remember that in tuberculosis of the body, wherever situated, peribronchial tuberculosis, old or recent, is apt to be found postmortem and such a good radiogram, can show antemortem. Further, in patients with non-tubercular pulmonary inflammations, abdominal carcinoma, esophageal carcinoma, etc., peribronchial glandular enlargement may occur, and I have seen several cases in which the shadows cast by such glands were clearly apparent in radiograms of patients suffering from these diseases, and this in the absence of any evident correlated physical signs. In such instances the possibility that they represent old tubercular peribronchial glands must always be borne in mind and the question determined by the whole clinical picture.

In two examples—one of lung carcinoma and one of bronchial carcinoma—the physical signs and the presence of multiple enlarged supraclavicular glands rendered the diagnosis easy, but the pictures obtained were so characteristic as to leave no doubt of the value of the plate in doubtful cases.

LOCULATED EFFUSIONS—INTERLOBAR EMPYEMA

CASE 6—A man, admitted into St. Luke's Hospital in Dr. Moffitt's service, complaining of pain in the right hypochondriac region. The pulse was hurried and a moderate degree of fever was present. The interne diagnosed cholecystitis. Investigation showed that we had to do with one of those cases of thoracic disease which simulate an intra-abdominal lesion.

Examination—Chest examination demonstrated posteriorly on the right side in the line of the great fissure a dull area, over which there were an increased superficial percussion resistance and a diminution of breath sounds. This area increased from day to day, finally becoming oval in shape. In increasing it evidently pressed on the lung tissue of the upper and lower lobes, giving the changeable physical signs that arise from the varying amount of air in the lung vesicles.

X-ray Examination—Considering that we were dealing with a case of interlobar empyema we made a radiogram. A large oval shadow with sharp edges, the periphery darker than the center was readily seen, the center corresponding pretty nearly to the normal position of the fissure. The right diaphragm was quite as low as the left, as though Nature had determined to make as much room as possible for the collection, thus avoiding tension. Operation demonstrated the correctness of the diagnosis.

This case was to me very instructive, inasmuch as I had been asked some weeks previously to interpret an almost identical plate made from a patient whom I had not seen clinically. The differential diagnosis of the plate seemed to rest between a cyst of the lung and a loculated collection of fluid dependent on a local pleurisy or a rib tuberculosis. I thought it unlikely to be a cyst, inasmuch as I would have expected a cyst of such size growing in the soft lung parenchyma to have been more rounded. I, therefore, considered it to be due to one of the two latter conditions. Later I saw a more recent radiogram of the same patient. The oval shadow had vanished, the lung was quite clear, but now there was a little fluid in the pleural cavity which finally disap-

peared In view of the correlated picture of the previous case and the two radiograms of this case, I believe it was a case of interlobar serous pleural effusion which had ruptured into the general pleural cavity and in that way a cure had resulted

So much has been written on the value of the x-ray in the diagnosis of aneurism of the arch of the aorta that I have little to add on this subject. However, I have never seen such an aneurism depicted on the plate (and I have seen many) which did not give rise to clinical signs and whose presence ought not to have been surmised previous to the radiographic examination I have watched patients in which I thought such to be the case, but they turned out to be examples of arteriosclerosis of the arch, the plate showing the characteristic knob on the left side In such connection I would again emphasize the mistake made by so many of not cultivating the sense of percussion, palpation resistance, in percussing out dulnesses in this area, especially is this method of value in cases complicated by emphysema which may otherwise hide the aneurismal enlargement But I do not doubt that there do occur small saccular aneurisms which exhibit no chest physical signs and which, of course, are distinctly visible on a good plate

I would like here to refer to a remarkable case which I lately saw An old man with Bright's disease had paralysis of one vocal cord I carefully overhauled his chest for indications of aneurism and could find none The interne, Dr Loos, made the postmortem examination and reported a small saccular aneurism He removed the heart and big vessels in mass with the contained blood I saw the specimens and noted the presence of the aneurism, which was about the size of half a marble We emptied the heart and aorta, and, lo! the pouch disappeared and its wall became in line with the adjoining walls, but remained somewhat loose Two other physicians then entered the room, neither of whom could see any indication of the pouch Such an occurrence must have been due to the wall at this point possessing enough elasticity to retract when once the dilating internal blood was removed, and thus opens up the question whether functional dilatations are not temporary aneurisms and whether the vessels do not sometimes change at death just as may the size of the heart chambers

I desire to add one word concerning dilatation or aneurisms of the descending thoracic aorta I have seen several patients who have complained of one-sided chest pains, pseudoanginal in character, but without the other usual accompanying symptoms of anginal attacks They have had this pain for years and have shown a markedly high systolic blood pressure In some of these patients presenting no physical signs apart from a markedly accentuated second aortic sound, dilatation of the descending thoracic aorta can be shown as it runs behind the heart, and, though I have carefully looked, I have been able to find no corresponding correlatable physical signs Potassium iodid in large doses alleviates and often dissipates the pain

THE PNEUMOTHORAX GROUP

CASE 7—Patient and History—A young man, apparently in good health, had been seized some weeks previously with sudden left sided chest pain Since then he had been somewhat dyspneic but had continued to get about

Examination—The left side of the chest moved less than the right though it was more prominent, the percussion note was hyper resonant, the respiratory murmur somewhat faint, the left diaphragm low and moved little or none. There was

no amphoric note, no amphoric respiration, no coin sound, no displacement of the heart and, because of the absence of these supposedly characteristic signs, an error was made in diagnosis

X-ray Examination—With the fluoroscope I was able to convince the doubters that a pneumothorax was present as the lattice work of the chest was unnaturally bright, and the lung could be plainly seen lying along the vertebral column It expanded a little at each inspiration and pulsated in an expansile manner apparently synchronously with the heart. Similarly in a considerable number of patients with pleuritic effusion I have been able by the use of the fluoroscope to confirm my clinical suspicions that air had been unintentionally admitted owing to bungling tapping

There is no doubt but that there is a tendency for physicians to rely too much on the presence of so-called pathognomonic signs in the diagnosis of disease This has been very apparent in the course of the work we have attempted to do and has been responsible for many diagnostic errors It takes some time before one can successfully inculcate in a new batch of senior students that there are practically no pathognomonic signs, but that the diagnosis must be made from a much broader standpoint, and in that inculcation the ray has been very serviceable

THE HEART AND PERICARDIUM

As is well known, the auricular and ventricular pulsations can be plainly seen with the fluoroscope and the size of the respective chambers noted, and thus percussion ability can be gauged and acquired I have not been able to time them, and in one thick-set patient with block heart the fluoroscopic examination was unsatisfactory In such cases multiple tracings are to me much more convincing than any fluoroscopist's opinion

In two patients referred for an x-ray chest examination I was able to suggest the presence of a pericardial exudate Both patients were ambulatory In one the pericardial exudate complicated a carcinoma of the mediastinum, in the other, lung and peribronchial tuberculosis No postmortem was allowed of the first, but the pericardial sac in the other patient contained 300 cc of fluid The diagnosis was suggested in both by radiograms As I had not previously clinically examined the patients I can not say what had masked the exudate We must admit, with Jones of Memphis, that many cases of pericardial effusions pass unrecognized I can not but believe that some of the big dilated hearts that have diminished so wonderfully in size under Nauheim or Schott treatment have really been instances of unrecognized pericardial effusion One example of this has lately come under my observation and its interpretation was plain The failure to recognize these cases seems to be due to neglect on the part of the physician

- 1 To suspect its possible presence
- 2 To examine the patient in both the upright and recumbent positions
- 3 To compare the apex beat and the outer limit of percussion resistance
- 4 To test for palpation sensitiveness

Some time ago I demonstrated plates which strongly suggested the existence of pericardial adhesions For some months we had been testing, in hospital and clinic, the value of the clinical signs supposedly indicative of their presence Our records were unfortunately burned With Tallant we found Broadbent's posterior systolic retraction present in many patients in which there was no suggestion of adhesions, and the autopsy none was found The position of the maximum retr

piration In a small number no such change occurred In these, other signs indicative of the existence of adhesions were evident, and it was in these that the radiograms also suggested their presence The clinical recognition of these adhesions is at times easy, in other cases difficult, and in the latter class the ray is of distinct assistance

ESOPHAGEAL DISEASES

In some of these the radiograms, if correctly interpreted, will be of assistance But we must never forget that esophageal tumors may pulsate and, in cases of abscesses, may actually show an expansile pulsation We will avoid error if we remember that any tumor that has given rise to difficulty of swallowing as its first symptom is almost certainly esophageal in origin, however much it appears on the fluoroscope to resemble an aneurism Again, in cases of esophageal pouches or dilatations consequent on spasm of the cardia, the radiogram will be of much service and will fulfill a function to which I have not alluded, viz prevent dangerous inquisitive diagnostic meddling The history of the patient, plus radiograms made with the pouch or dilatation, empty and then with the pouch containing milk with bismuth in suspension will render the diagnosis so easy as to make it superfluous to fiddle with double tubes or queer sounds, by the use of which perforation or ulceration may be produced. A physical sign, which as far as I know, has not been hitherto described, occurred in a case of an esophageal pouch and consisted in a change of pulse rhythm according as the pouch was empty or full The change was more marked on deep respiration, and is, of course, readily explainable by the proximity of the pouch to the vessels, it, when full, exerting pressure on them. Reflection suggests that this pulse variation might be confined to one side, depending on the position of the pouch

In esophageal diseases the correlation will be between the history, the symptoms and the radiogram, and hence a full history with events chronologically arranged is of extreme importance

DISEASES OF THE ABDOMEN

The diagnostic value of the x-ray in the diagnosis of renal, ureteral and bladder calculi and of vertebral and iliac disease is so universally recognized that little comment is here necessary But we must not forget that shadows simulating those cast by calculi have been thrown by calcified retroperitoneal glands, by sesamoid bones, etc., so that some surgeons have even gone so far as to introduce a leaden stylet into the ureters and then photograph it *in situ* in order to determine if the doubtful shadow lay in the line of the ureter shadow Such a proceeding is rarely necessary if we will properly correlate our clinical and radiographic findings and if we remember that segregation of the urine or, better, ureteral catheterization is as much demanded in the diagnostic study of these cases as radiography Not infrequently the shadows of the kidneys themselves can be distinctly outlined on the plate, their relative size compared and any irregularity of the border noted.

I have never obtained definite radiographic outlines of the normal liver, but in cases in which pathologic changes have taken place in that organ modifying its density I have frequently succeeded in plainly outlining it on the photographic plate Thus at the San Francisco County Medical Society I lately demonstrated a series of radiograms showing

1 A Riedel's lobe.

2 A much enlarged liver which turned out to be the result of syphilis

3 Another in which the enlargement was due to a liver abscess

4 A series in which a corset lobe was plainly visible, running down toward the iliac crest.

5 A number in which the shadows cast by intrahepatic gallstones were distinct

Of much help in the interpretation of some of these plates was the position of the large intestine, in liver enlargements its shadow ended at the lower border of those enlargements and, however big the liver was, the normal oblique line of its lower border was maintained In kidney tumors, on the other hand, the bowel ran up alongside the tumor toward the shadow cast by the liver above The nature of these masses could be readily detected by clinical means alone if the clinician persevered or varied his methods till he obtained complete relaxation of the abdominal wall, and then always remembered to trace the whole extent of the lower liver border These points, however, received altogether insufficient attention from those working in the clinics Similarly I have succeeded in registering on the plate a huge leukemic spleen, the notch being distinctly visible in a patient who had been supposed to possess a tumor of renal origin The blood picture was pathognomonic, however

We can learn much of the position of the stomach, its size, its division into pathologic compartments and the likely therapeutic value of an abdominal support from radiography I have not yet succeeded, as Hemmeter has, in getting radiographic evidence of the presence of a gastric ulcer, but have several times been guided to a stomach carcinoma

I have up to now received little aid from the ray in the diagnosis of brain lesions But it is probable that the technic which allows one to get beautifully clear anteroposterior views of the cranial air sinuses will help considerably in the differential diagnosis of the cause of the various headaches.

In conclusion I would suggest that

1 Bilateral local functional spasm of the diaphragm can occur

2 An appreciation of percussion resistance is of more assistance in diagnosis than is the percussion note.

3 An interlobar pleural effusion is sometimes serous, and hence the term interlobar empyema is a misnomer

4 So-called functional dilatation of blood vessels are really temporary aneurisms, and that the vessels may change at or after death.

5 As Tallant has shown, many persons present the Broadbent retraction of the left lower posterior chest wall In those cases in which there are no adhesions I have found that the position of the maximum retraction varies with the respiratory phases, being higher during expiration, lower during inspiration, while in cases with adhesions this change does not happen

6 In patients presenting a pouch of the esophagus a change of pulse rhythm may occur, according as the pouch is empty or full, this variation being better marked during full respiration

7 Pericardial effusions are often unrecognized and probably some cases of dilated hearts which have undergone extreme reduction in size from the Nauheim treatment have been instances of pericardial effusion

8 The correlation of clinical and Roentgen diagnostic work as outlined will be of value as follows

A It will much increase the average physician's percentage of successful diagnoses

B It will enable even the expert clinician to assert that certain lesions are present whose existence he could otherwise only suspect, as e. g., peribronchial tuberculosis, central patches of pneumonia where the feeding bronchus is blocked, certain cases of bi- or trilobulated stomach, and it will assist him to maintain a uniform standard, since it will tend to save him from errors made when he is brain weary and hurried

C It will be of some assistance in the relations between physician and patient

D It will sometimes render unnecessary dangerous inquisitive diagnostic methods, as, e. g., in esophageal pouches or dilatations

E It will assist the clinician in his endeavors to develop a high degree of clinical skill, helping him to sift his clinical armamentarium

F It will aid considerably in teaching especially where it is necessary to correct rather than to instruct

ADDENDUM

In exposing many hundreds of patients for diagnostic purposes I have produced one burn. That was during the early work and should have been avoided. The burn healed with a good scar. I have seen no other evil results in patients. The summation of exposures renders the operator's task risky and dangerous. Protection must be thorough, and I would advise the clinician to have nothing whatsoever to do with radio therapy

MULTIPLE NEURITIS (NON-DIPHTHERITIC) IN CHILDREN *

H. M. THOMAS, M.D., AND H. S. GREENBAUM, M.D.

BALTIMORE.

Multiple neuritis in children is generally considered a rare condition. In Starr's¹ analysis of 154 cases of multiple neuritis non-diphtheritic, none of the patients were under 15 years of age. In Remak's² series of 94 cases, 9 patients were between 10 and 20 years of age, but none below. Gowers³ refers to it as extremely uncommon, as does Oppenheim.⁴ Sachs⁵ considers the question thoroughly and appears to have seen a number of cases, but gives no definite data.

Holt⁶ speaks of the chief cause of multiple neuritis in children as being diphtheria, although it is occasionally seen after infectious diseases. He states that the metallic poisons rarely cause multiple neuritis in early life, and the same is true of alcohol. He refers to certain cases which have been assigned to simple exposure to cold. Buzzard⁷ thinks it probable that a number of cases of so-called infantile paralysis are examples of

multiple neuritis, especially those in which the patients make an exceptionally good recovery after a very long delay.

Cases of multiple neuritis in children have occurred in epidemics, usually associated with epidemics of anterior poliomyelitis. Medin⁸ reports a most interesting series of cases which show this association. He studied cases occurring about Stockholm, viz. 43 or 44 epidemic cases occurring in the year 1887, 29 sporadic cases occurring between 1888 and 1894 and 21 epidemic cases occurring during 1895. These were almost all cases of anterior poliomyelitis, but in the epidemic cases in 1887 he saw 6 of multiple neuritis and 2 during the epidemic of 1895.

The cases which Hammond⁹ reported in 1895 occurring in an epidemic at Bridgeport, Conn., seem to have been almost exclusively cases of multiple neuritis. He recorded 10 in which the patients ranged in age from 4½ months to 4½ years, the youngest child died of inanition and dysphagia, the others improved. Caverly¹⁰ and MacPhail¹¹ report a series of 126 cases of infantile paralysis occurring during the summer of 1894 in the city of Rutland, Vt. These cases were for the most part anterior poliomyelitis, "but in some there were elements strongly suggestive of multiple neuritis." Blackall¹² reports an epidemic in Australia. His 6 cases seem to have been cases of multiple neuritis. These cases occurring in epidemics are supposed to be due to some acute microbial infection, which it seems at times affects the spinal cord, at times the peripheral nerves and more rarely the brain and its membranes.

One of us (Dr. Greenbaum) has collected from the literature and tabulated 138 cases of non-diphtheritic multiple neuritis occurring in children. These cases are made up as follows:

	INFECTIOUS CASES			Not mentioned.
	Total	Boys	Girls	
Grippe	3	-	1	0
Measles	8	-	5	1
Typhoid	5	4	1	0
Tuberculosis	1	1	0	0
Syphilis	2	0	0	2
Whooping cough	7	3	2	2
Chickenpox	1	0	0	1
Scarlet fever	6	2	4	0
Miscellaneous	1	6	5	4
	48	20	18	10
	TOXIC CASES			
	Total	Boys	Girls	
Lead	19	11	8	2
Alcohol	5	-	0	0
Carbon monoxide	1	1	0	0
Arsenic chorea	1	4	13	7
Arsenic non chorea	4	2	1	1
	48	23	26	7
Ascending palsy	9	3	3	3
Unknown origin	31	11	9	11
	42	14	12	16
Total number of cases				18

In addition to these cases, Starr¹ says

All alcoholic drinks are not equally prone to produce paralysis. I have seen a case in a child of three years who had been given beer several times a day for several weeks.

Sachs⁵ states

I have seen several cases of this description (malarial neuritis) in children who were brought to my clinic from the swampy parts of Long Island.

* I read in the Section on Nervous and Mental Diseases of the American Medical Association at the Fifty-seventh Annual Session June 1906. This paper was accompanied with a tabulated report of 138 cases for which THE JOURNAL could not give space. The author offers to send a reprint of the complete article including the case reports, to anyone on request. The entire article will also appear in the volume of Transactions of the Section on Nervous and Mental Diseases of the American Medical Association 1906.

Webber¹³ says

Of all the patients, the youngest was nine years old. This is the youngest child in the list.

According to Oppenheim⁴

I have seen it several times in children from four to six years old.

It seems to us that the disease is probably not so uncommon as has been generally stated, but that the cases are not reported either because they are mistaken for ordinary infantile paralysis or else are not thought sufficiently interesting. Our experience in the Neurological Dispensary of the Johns Hopkins Hospital is somewhat unusual in two respects: 1, in the rather small number of cases of multiple neuritis in general, 2, in the large proportion of children we have seen among them. In the past 16 years, with an average of 1,200 new neurologic cases a year, we have seen only 21 cases in which the diagnosis of multiple neuritis (non-diphtheritic) has been made, and, out of these, 8 have occurred in children under 12. This does not include hospital cases where the severe adult cases are more apt to be sent directly. Among ward cases was one case of a child which was not recorded in the dispensary. The cases which we have to report include 5 girls and 3 boys, their ages being 3, 4, 5, 6, 9, 10, 10 and 12, respectively. Three of them followed typhoid fever, two of them having already been reported by Dr Osler. In the other 5 cases we were entirely unable to determine any etiologic factors.

The clinical picture in all the cases was typical of multiple neuritis. The onset was generally acute with lassitude, fever and loss of appetite. Both arms and legs were affected in every case and practically symmetrically. Electrical changes were generally present and the deep reflexes were lost in every case but Case 4, that of a girl of 12. We were never able to explain the persistence of the reflexes in this single case, unless it might have been a case of lead poisoning. In lead cases we have noticed that the knee-jerks are apt to be exaggerated even at times when the legs were also themselves involved. All the patients improved, the arms improving first in every case except Case 4, the girl referred to, in whom the legs improved rapidly, but in whom, now 9 years after the onset, there is a stationary bilateral atrophic paralysis of the intrinsic muscles of the hands. This perhaps also indicates lead poisoning.

In a number of children there has been a tendency to the development of a slight contraction of the calf muscles. One of the patients showed a definite recurrence, and one two or three relapses.¹⁴ The recovery in all was slow, extending over several months. We include only short abstracts of the cases.

CASE SUMMARIES

CASE 1—Previously reported by Dr Osler

Patient—D S boy aged 9, was admitted to the Neurological Dispensary, Nov 1 1893

History—Patient had a severe fever of three weeks' duration during convalescence, weakness of arms and legs with finally complete paralysis, foot drop and wrist drop, great soreness of the muscles, progressive improvement, complete recovery after persisting for more than a year.

Present Condition—Patient was seen April 17, 1906 had remained well, in perfectly normal condition except perhaps some slight weakness of the anterior muscles of the

lower leg. "Can raise himself on his toes but not on his heels."

CASE 2—Previously reported by Dr Osler

Patient—G R, boy, aged 10, was admitted to the Neurological Dispensary,

History—In September, 1894, he had had a severe attack of typhoid fever, in third week soreness in leg, gradual paralysis of arms and legs, on admission feebleness of arm muscles, grasp extremely feeble, double foot drop, typical step page gait, reaction of degeneration in leg muscles, great muscular soreness, arms and legs, discharged Feb 4, 1895, after considerable improvement.

CASE 3—Referred to by Dr Osler as a case following exposure to cold.

Patient—H. J F, aged 10, was exposed to wet and cold in September, 1894. On following morning complained of weakness in arms and hands. In the afternoon his legs were weak, by night he could not walk, was in bed for a month with fever and delirium. "He became perfectly helpless, but never at any time were there symptoms of typhoid fever."

Clinical History—Patient was admitted Jan 2, 1895. He was then pale and weak, walk typically steppage, cranial muscles, neck, shoulder and upper arm muscles all good, muscles of wrist, weak, dorsal flexors weaker, fingers were paralyzed, in legs, typical foot drop, could not extend or flex the ankles, there was no particular sensitiveness of the muscles, sensation appeared normal, deep reflexes were absent, electrical changes in the weakened muscles.

Discharged from hospital, March 23, greatly improved. Returned later, in 1897, with arms perfectly normal, still some weakness of the ankle. In 1898 the right foot was almost completely normal, still some weakness on the left side.

CASE 4—Patient—L N, girl, aged 12, was admitted to the Neurological Dispensary in August, 1897, sick with fever and vomiting and pain in limbs.

Examination and Clinical History—On examination she presented a typical picture of multiple neuritis, double wrist and foot drop, except that the deep reflexes were all exaggerated. She could not sit up in bed, arms and legs seem to have been extremely weak. By September she had improved somewhat, could sit up and walk with assistance. Arms and legs were still very weak.

Subsequent History—We were never able to find any etiologic factor, although we inquired diligently into her surroundings. We saw her constantly from 1897 to 1901 and infrequently since. She improved very greatly, particularly in regard to her legs which became normal. She was examined this year, is in excellent health, no abnormality about the legs, but her hands show a symmetrical atrophy, with loss of electrical response. This has been present and has not increased for the last eight or nine years. The deep reflexes are present and active, but not exaggerated.

CASE 5—Patient—N D, girl white, aged 5, came to dispensary complaining of pain in legs and inability to walk, May 31, 1900.

History—Patient had had good surroundings, no indication of any source of poisoning, she had always been a nervous child. On May 1 she became listless and feverish, appetite was poor, complained of pains in legs and arms, arms and legs became weak, manipulation of arms and legs was painful, when she entered the hospital she had double wrist drop (slight), triceps reflex was present, double foot drop, unable to walk, slight knee jerk. Decreased electrical excitability in arms. Partial reaction of degeneration in legs.

Subsequent History—Condition improved first in arms, she walked in September, was discharged from hospital, Oct 18, 1900. During her stay in hospital she had irregular temperature, 101.5 being the highest. Child was fairly well through winter, but in summer of 1901 there was a recurrence of the neuritis which lasted a little over a month. She was examined in March, 1906. There have been no other recurrences, condition of her muscular system was practically normal, slight contracture of the gastrocnemius on each side, instep slightly more arched than normal, electrical reactions were normal.

CASE 6—W E girl aged 3, white

History—Child had been rather sickly. In February, 1905,

¹³ Multiple neuritis. Archives of Medicine vol xii p 42

¹⁴ Since the paper was read this patient had a sudden attack of some acute disorder. The paralysis seemed to recur again and the patient died.

was operated on for swollen glands, in March had double pneumonia, during April and May was perfectly well. No source of poisoning was discoverable. In June she became fretful, had no appetite, was easily tired. In July she suddenly collapsed, arms and legs weak.

Clinical History—Patient came to hospital Aug. 3, 1905, when she could hardly sit up. There was typical bilateral wrist and foot drop, reaction of degeneration in muscles below elbow and knee, deep reflexes were absent, muscles were tender on pressure. Patient was given galvanism and massage daily. In a month her hands began to improve. By November she could stand alone and walk by holding her mother's hands. Deep reflexes in arms present, knee jerk present, but ankle reflexes were not obtained. Condition continued to improve, but on December 6 there was a distinct relapse, particularly in the legs. Again began to walk December 18, and after that improvement was continuous. Note on April 12, 1906, records almost complete recovery, except slight contracture in the calf muscles.

CASE 7—History—A S, girl, aged 4, white, of a good German family, had had measles in May which lasted for two weeks. About the middle of June, 1905, she began to be fretful, had pain in stomach back and legs, vomited gradually lost power in walking and in a week was entirely unable to also unable to use her hands.

Clinical History—She was brought to the dispensary Nov. 11, 1905. There was no cause ascertainable except, perhaps, that she had been given "a mouthful of beer two or three times a week." There was bilateral wrist drop, also some muscular atrophy, deep reflexes were absent, there was bilateral foot drop. Movements of upper arm and legs above knee were normal. Calf muscles were slightly contracted. On left side knee jerks were absent, right, just obtained. There were no reflexes from ankles. Pressure over muscles and nerves in arms and legs caused no pain. Typical reaction of degeneration in muscles of arms and legs.

Galvanism and massage daily. On November 19 the patient walked with typical steppage gait. She improved steadily. In March, 1906, the hands were nearly normal and the walk good. There was slight contracture of the gastrocnemius. In April, 1906 knee jerks were normal.

CASE 8—Patient—B F, girl, aged 6 from West Virginia, was seen in the dispensary with Dr. Baer.

History—Patient was a strong child up to her illness with typhoid fever Oct. 8, 1905. She was very ill, had two relapses, became weak some time during the illness, just when is not known. She was sent to St. Mary's Hospital, Clarksburg, W. Va., Nov. 17, 1905, at which time both arms and legs were paralyzed. She improved greatly, left the hospital Feb. 18, 1906.

Examination—On May 26, intrinsic muscles of the hands were slightly atrophied, muscular strength was fair. Deep reflexes were doubtfully obtained, she walked with the typical steppage gait, strength of the hips and knees was good, there was marked weakness in flexors of ankles, the extensor calf muscles were stronger, knee kick was absent on right. Doubtfully obtained on reinforcement on left, ankle reflexes were absent, plantar stimulation gave no response. Pressure over leg muscles was not painful, electrical changes in legs were present but not definitely determined on account of extreme irritability of child.

ADDITIONAL CASES

A case seen in the ward of the Johns Hopkins Hospital has already been reported¹⁵ because of its interest in relation to generalized lead paralysis.

CASE 9—A girl, aged 5½, was in the habit of scraping the cans in which the food came. Her arms had been weak for three months but two days before admission her legs became so weak that she was entirely unable to walk. There was a lead line on her gums. Knee jerks were normal. Unfortunately she remained in the hospital only two days.

CASE 10—R L, girl aged 8, had multiple neuritis follow-

ing chorea and arsenic. Patient was seen with Dr. Cary Gumble, who will publish it in detail later.¹

History—During August and September 1897, she had slight attack of chorea and was given Fowler's solution in seven drop doses. She took it in two courses and received in all 504 drops in about one month. On September 27 she began to lose power in legs and to complain of pins and needles.

Clinical History—On October 1 she was admitted under Dr. Gamble's care to St. Joseph's Hospital. She had an arsenical skin eruption and complained of pins and needles in the calves of her legs, which were almost completely paralyzed. There were sensory changes over legs. Nerves and muscles were sensitive. Her condition remained practically the same until on October 18, when she began to complain of tingling in fingers, and on October 21 both hands became paralyzed. Next day she began to have difficulty in breathing, with rapid pulse. This was relieved by electricity, but the attacks recurred. On October 28 it was noted that the diaphragm was paralyzed. She died October 30.

SYMPTOMATOLOGY

From a review of these cases and of the cases found in the literature, it appears that the clinical picture of multiple neuritis in children does not differ in any material manner from that presented by the disease in adults. Sensory troubles are difficult to determine in children, still subjective pains, paresthesia, pains on pressure over nerves and muscles, and pain on moving the limbs, either actively or passively have all been described. Objectively, a decrease in the sense perceptions to touch has been found, together with pain and temperature as well as a delay in their conduction. The sensibility has been noted as normal in a number of cases. Sensory disturbances when present do not as a rule persist for a long time.

Electric changes have usually been found, although in certain of the cases the reaction has been noted as normal. The change may be only a decrease in excitability but usually one of the grades of the reaction of degeneration is present. Atrophy is generally present and may be permanent. The deep reflexes are usually lost but in certain cases have been noted as normal. The reflexes, if lost, usually return as the patient gets well.

The distribution of the paralysis is usually widespread and symmetrical, affecting both the upper and lower limbs but the legs are generally more severely involved than the arms. This is especially true in cases following infectious diseases. In the lead cases both the upper and lower limbs were involved 15 times. In two, the legs were alone involved. This confirms the statement which is generally made that lead paralysis in children is apt to involve the legs. In one of these cases one side alone was involved. In the alcoholic and arsenic cases the paralysis has affected both the upper and lower limbs but here again the legs were more severely affected. The arms and hands are seldom involved alone and in recovery they usually recover before the legs and feet.

DIFFERENTIAL DIAGNOSIS

In diagnosis, the chief difficulty is to differentiate it from poliomyelitis but the following points will be of help.

1 Multiple neuritis comes on more insidiously than poliomyelitis, but this is not always the case.

2 The cause in multiple neuritis may be known such as metallic poisoning or a previous acute illness. In poliomyelitis the cause is unknown.

15 Johns Hopkins Hosp. Bull. 1904, xv, p. 170.

16 This case is referred to

in practice.

3 Fever is more apt to occur at the onset of poliomyelitis

1 Subjective pains may occur in either but are perhaps more apt to occur in multiple neuritis and to last longer

5 Objective disturbances in sensation although difficult to estimate in children, point to multiple neuritis Pain on pressure over muscles may occur in either

6 Poliomyelitis may attack a single limb or the limbs in any combination and involve any group of muscles, but the paralysis is practically never bilaterally symmetrical and rarely affects all four limbs at one time A widespread symmetrical paralysis is very characteristic of multiple neuritis

7 Complete or nearly complete recovery is the rule in multiple neuritis, it is the exception in poliomyelitis

8 A return of the knee-jerks and of the electric reactions to normal suggests the existence of multiple neuritis

Besides poliomyelitis the disease may in certain cases have to be differentiated from Friedreich's ataxia, tabes, hysteria, interstitial neuritis of Dejerine, progressive muscular dystrophy, myelitis rickets, Pott's disease, progressive muscular atrophy and meningitis but in these the history and associated symptoms makes the differentiation easy, and in none of them do we see the typical bilateral foot-drop and wrist-drop

PROGNOSIS

Prognosis is good We note complete recovery in 58 of the cases in literature, in 46 partial recovery at the time of the report In one case recovery failed to take place and in 33 cases no mention is made as to the course of the disease Fourteen cases were fatal two meningitic, two alcoholic, one leuc, one unknown, six ascending paralysis, one angina follicularis one syphilis Of these four have autopsy reports as follows

Autopsy Reports—Kahler and Pick Nothing abnormal in nervous system

Kast Patient died of aspiration pneumonia In the microscopic and macroscopic investigation the central nervous system was found normal On the other hand striking degeneration of the peripheral nerves, especially the hypoglossal recurrent laryngeals etc The exact investigation of the rest of the peripheral nerves is not given, however it is conjectured that there are peripheral processes giving a symptom complex which clinically imports a spinal or bulbar disease

Campbell Pneumonia tuberculosis, etc, disseminated degeneration of the myelin containing fibers through the white substance of the spinal cord and especially prominent in the posterior columns Further, partial degeneration of the anterior and posterior nerve roots and finally degeneration in the peripheral nerves which to be sure was not of very high degree but was developed stronger peripherally

Legeron-Lauvier at autopsy found the nerve centers normal

We note that five of the cases are recurrent scarlet fever (Figs-Bissette-Eglise) whooping cough (Surmay) unknown (Chapin)

TREATMENT

In treatment the cause if possible should be removed A nourishing diet should be given the bowels kept open Rest in bed in the early stages quinin in the malarial cases massage electricity passive exercise mild gymnastics and hydrotherapy are helpful A tonic may be given The pains usually disappear spontaneously if they do not hot baths or bromids will relieve them If

a permanent foot-drop or wrist-drop remain, the orthopedic surgeon may be consulted

DISCUSSION

DR W N BLISSARD Boston said that he has seen a number of cases of this character, and asked Dr Thomas if it is not possible that some of these unexplained cases were really due to diphtheria In some of his own cases he has found it exceedingly difficult to discover the preceding disease, but many of them have been traced back to diphtheria

DR H M THOMAS, Baltimore, said that it is always hard to exclude anything absolutely, but that the cases to which he referred were not regarded as diphtheritic The paralysis was different from that characteristic of diphtheria The throat was not involved and there was no paralysis of accommodation There must have been some toxin the cause of which was unknown Certain cases of multiple neuritis in children have occurred in epidemics usually in association with epidemics of anterior poliomyelitis, and it would look as if the same poison might be a cause of the two conditions

A NEW MODE OF TREATMENT FOR INOPERABLE CANCER OF THE UTERUS BY MEANS OF ACETONE*

GEORGE GELLHORN, M.D.

Gynecologist to St. Louis Skin and Cancer Hospital and St. Luke's Hospital Instructor Medical Department Washington University
ST. LOUIS

In recent literature there is a remarkable dearth on the subject of the treatment of inoperable cancer The interest of the profession seems to be absorbed by the problems of earlier diagnosis and more radical operation in cases which are still within the reach of the surgeon Yet so long as the usual means of treatment fail to relieve in any degree the deplorable fate of the unfortunate ones who are beyond that reach the attention and energy of the profession must also be claimed for improvement along the lines of treatment of inoperable carcinoma

A rapid survey will substantiate these claims as far as inoperable cancer of the uterus is concerned The much-heralded trypsin treatment has not come up to its promises It has utterly failed in my cases and in those of most of the other observers Roentgen-ray therapy in uterine cancer thus far at least has not accomplished any beneficial results The experiences gained in the St. Louis Skin and Cancer Hospital prove that the Roentgen rays can not reach and destroy malignant growths in the cavities of the body

The soundest suggestion of recent years is undoubtedly that of Lomer who advises curetting and thermocauterizing the diseased area thoroughly and repeating this procedure at regular intervals of four weeks Thus by an extensive cauterization of the cauterized tissues the remaining cancer cells impaired as they are by the effect of the burning heat would be deprived of their necessary nourishment Unfortunately, this plan of treatment can not easily be carried out in practice There are but few patients in my experience who will submit to the periodical operations and I am not aware that Lomer's valuable suggestion has been confirmed by many reports from other quarters

The hosts of other remedial agents need only be mentioned in order to be dismissed as absolutely useless

Lomer in the St. Louis Skin and Cancer Hospital

Thyroid feeding, administration of drugs such as chelidonium majus application of calcium carbide, electricity, the cancerin of Adamkiewicz injections of various sera or of irritating substances such as alcohol acetic acid, corrosive sublimate, methyl violet venom of the cobra di capello oil of turpentine, and arsenious acid

The reader must bear in mind that with the exception of trypsin and, perhaps of the Roentgen rays, which aspired to a radical cure all these modes of treatment merely aimed at making the patient's life endurable so long as it lasted. The primary object was and still is, to reduce the weakening hemorrhages and to check the intolerable stench of the discharge. Yet our pitiable helplessness in this respect can not be better illustrated than by the fact that two surgeons (Gottschalk and Kuestner) independently of each other devised an artificial occlusion of the vagina (colpocleisis) as a last though but temporary resort.

It is this distressing odor that has defied all our efforts. It is this odor that, in reality, constitutes the most formidable symptom of the disease that makes devoted children wait almost impatiently for the death of a beloved mother, and that tends to break up all ties of family and friendship.

For the same reason, such patients are not willingly admitted in a general hospital. In an institution of the nature of the St. Louis Skin and Cancer Hospital they seriously menace the workings of the hospital. Attending physicians as well as nurses suffer from the unbearable odor, and operable patients or those afflicted with less loathsome forms of cancer are easily driven away.

There was, then every reason for trying to improve the existing conditions. For the last year and a half I have tried or tested a number of chemicals, without however receiving more than a passing encouragement. I may discuss the relative merits of these remedies in a later publication. In this report I merely wish to call attention to a new mode of treatment which thus far has yielded unexpectedly good results and which in the limited number of cases in which it has been employed seems to have successfully met the chief requirements in the treatment of inoperable cancer of the uterus.

This treatment consists of the methodical application of acetone. Acetone (Dimethyl-ketone, C_3H_8O) may be found, in traces in every normal urine and it increases in fever with starvation or with a purely meat diet. It is familiar to the clinician from its occurrence in the urine in cases of diabetes mellitus in certain forms of digestive disturbances, and in some cases of carcinoma. Recently it has also been found in the urine of patients with ectopic gestation.

Physically acetone is a transparent, colorless mobile and volatile liquid of a characteristic ethereal odor and a pungent, sweetish taste. On the skin it causes the sensation of cold. It has found extensive use in laboratory technique for hardening tissues prepared for microscopic examination. Tissues shrink rapidly in acetone owing to its intensely hygroscopic qualities and, if left in the fluid for more than half an hour they are as a rule too hard for the microtome knife.

It was my idea to utilize these laboratory observations for practical purposes. If the ulcerating surface of the cancer could be hardened *in vivo*, the discharge could be checked until the escharotic portion would be cast off. The resulting free surface could then again be hardened. It would perhaps also, be possible to harden deeper portions or even the entire tumor thus rendering the malignant growth temporarily harmless.

The treatment should, if feasible be preceded by a

thorough excochleation of the ulcerating area. The curetted cavity or crater is then carefully dried with cotton sponges and from one-half to one ounce of acetone is poured into the wound through a Ferguson or other tubular speculum. For this purpose the pelvis of the patient must be raised as in Trendelenburg's position. The narcosis may now be interrupted and the patient be left in this position for from fifteen to thirty minutes. Next, the acetone is permitted to run out through the speculum by lowering the pelvis of the patient and the cavity is packed with a narrow gauze strip soaked in acetone. The healthy mucosa of the vagina and the vulva are cleansed with sterile water and dried.

After this preliminary curetting and craterization the regular treatment which requires no further hospital care, is administered twice or three times a week beginning the fourth or fifth day after the operation. This is done without narcosis and may be given with the patient in bed or on the ordinary examining chair or table in the office. The pelvis of the patient is raised and the tubular speculum is inserted into the cancerous cavity. With the progressive diminution of the crater smaller specula are gradually employed. The speculum is filled with acetone and held in place by the patient's hand for half an hour, and is then emptied in the manner described above. Care should be taken to prevent the acetone from running over the vulva or perineum.

The immediate effect of this simple procedure is the following. Any slight oozing is checked almost instantly. The surface of the crater is covered with a thin whitish film, wherever there was an extravasation of blood, the discoloration is light brown. The normal vagina is not appreciably irritated. On the vulva mucosa and the outer skin an excess of acetone produces a faintly white discoloration which soon disappears. There is no pain from the cauterization save a slight stinging sensation if the acetone has touched the skin. This, however passes away rapidly if the affected parts be washed with cool water. In no instance have I been forced to employ any anodynes.

The more remote effect manifests itself in a marked reduction of the intense odor. The discharge, at first becomes more watery and gradually disappears. With it disappears the former stench. At the same time the hemorrhages fail to recur—at least in the cases thus far treated. After two or three weeks of this treatment I have noticed a considerable diminution in the extent of the wound cavity. The walls of the latter become smooth and firm. There were no more polypoid excrescences, nor could the finger remove any friable tissue.

Owing to the absence of weakening hemorrhages and discharge the general somatic condition of the patients improved visibly. On the other hand, sensations of pain caused by the extension of the cancer to adjoining organs or nerve trunks beyond the reach of the acetone were not relieved, these required now, as before, administration of anodynes. In order to determine if there was any absorption of acetone into the organism frequent examinations of urine were made both before and during the course of treatment. These examinations have, so far, remained negative.

Of the limited number of cases thus treated one or two may serve as illustrations.

CASE 1—Mrs. F. S., aged 42.

History—Present illness began June 27, 1906 with profuse hemorrhages, for which she was "cauterized" by a physician in Texas, yet the discharge continued and she grew rapidly weaker. She came to St. Louis and was

Oct. 14

Nov. 30, 1906, without relief. She had persistent bloody discharge, severe pain in the lower abdomen which prevented sleep, and dysuria. On Jan. 20, 1907, the patient was admitted to St. Louis Skin and Cancer Hospital. She was greatly emaciated and unable to walk.

Examination—Pulse was rapid and hardly perceptible. Anemia was excessive. Hemoglobin, 35 per cent, erythrocytes, 2,907,000, leucocytes, 33,320.

Urine—Specific gravity was 1004, and the urine contained large quantities of albumin and blood corpuscles.

Abdomen—The lower abdomen was filled with a hard, immovable tumor which extended one inch below the umbilicus. Within the vagina, about one inch above the entrance, there was an annular constriction, beyond which the examining finger entered a wide cavity, the sides of which apparently were formed by the pelvic walls. This cavity was filled with soft, friable masses which seemed to project from above downward. There was a profuse watery, foul discharge which soon took on the character of a hemorrhage. Excessive pain prevented further exploration.

Diagnosis—Fibroid of uterus and carcinoma of cervix.

Operation—On Jan. 24, 1907, under ether narcosis, a thorough excochleation of the extensive cavity was done. The soft masses within were largely necrotic and greenish in color. A large amount of tissue was removed by the curette. The cavity was packed with gauze saturated with acetone. The condition of patient was alarming and stimulants were necessary. A microscopic diagnosis of carcinoma was made.

Postoperative History—Jan. 25, 1907, the dressing was removed. The patient was comfortable. By February 7, 1907, she had been receiving acetone treatment of one half hour's duration three times a week. There was no odor in the room, there was no hemorrhage, and only very slight discharge. The patient had not had sufficient pain to require opiates except one night. In the place of the former soft, friable masses, the crater was found to have contracted a great deal and scarcely admitted a finger. The walls were irregular from projecting areas of firm tissue with smooth surfaces which did not bleed.

February 19. Treatments had been continued and patient was gaining in strength and was able to walk about.

February 23. The patient had been having some paroxysms of pain in the abdomen similar to those before entering, but she thought that the pain was not so constant, at times she had several days of freedom. This was not the case before entering hospital, when pain was rather continuous. There was absolutely no odor, at times there was a slight watery discharge. There had been no hemorrhage since the acetone treatment was instituted. The walls of the crater were contracting and were so firm that the examining finger or manipulations with sharp edge of glass speculum did not cause any bleeding. In part the walls were covered with a grayish membrane easily detached and leaving no bleeding site, in other places the walls were clean and bright red, and did not bleed on pressure.

CASE 2—Mrs. R. W. aged 33.

History—She had been bleeding from the vagina almost continually for the previous three months and had had severe pain in the lower abdomen for about two months. There had also been rapid loss in weight.

Examination—This revealed a large cauliflower excrescence of the cervix uteri with involvement of the anterior vaginal wall and left parametrium. Local application of lotio pancreatis (Faurel) three times a week for about two months, failed to give any relief. On Oct. 10, 1906, she was examined by Professor Wertheim of Vienna, during the latter's visit to St. Louis and he pronounced her condition inoperable.

Operation—On Oct. 13 and Dec. 3, 1906, a thorough excochleation and thermocauterization was done, followed by slight temporary improvement. A microscopic examination showed carcinoma.

Later History—On Jan. 5, 1907, she was readmitted to hospital. She had recently had several profuse hemorrhages. There was a stinking discharge, and pronounced cachexia. The tumor at this time involved the entire upper half of the vagina and extended deeply into the left broad ligament. The tissues were friable and bled freely after examination.

January 11. Another thorough excochleation and thermocauterization was done under ether anesthesia.

January 17 to 28. Local application of acetone was made through a tubular speculum every other day. The odor was considerably lessened and there were no hemorrhages. At times there was a pinkish discharge.

January 31. Menses occurred, normal amount.

February 6 to 12. Acetone treatment was continued. There was slight discharge, with no odor and no hemorrhage.

February 21. The patient had been at work constantly prior to this date, reporting three times weekly for treatment. She had good color and there had been no loss of strength in the preceding six weeks. The crater walls had contracted so much that the narrowest speculum could not be inserted readily. The induration extended on the anterior vaginal wall to about 1½ inches from meatus, and on the posterior wall to about 2 inches from the mucocutaneous border. The crater was about 1¼ inches in depth. Its walls were firm and did not bleed on digital examination. The involvement of the left parametrium had not increased, rather the contrary. The entire mass (uterus plus periuterine involvement), seemed somewhat more movable. There was no odor or bleeding.

February 22. Under ether anesthesia the crater was freely curetted, but only a small amount of tissue could be scraped away. The scrapings were firm, bleeding was very slight. This excochleation was in marked contrast to former curette treatments on the same patient when large quantities of very friable tissues were removed with abundant hemorrhage. The operation was followed by application of acetone.

March 5. Undisturbed convalescence. The patient looked and felt very well. She had been menstruating normally for three days.

March 15. She had received treatment regularly three times a week and felt well. She stated that intercourse was indulged in without any bleeding. The vagina was very narrow. There was absolutely no odor nor discharge. The patient was kept under regular treatment.

EPIORISIS

These two patients suffered with unmistakable carcinoma of the uterus, clinical manifestations and microscopic evidence talked. In both patients the disease had long since passed beyond the reach of any radical operation and had even consumed the greater part of the vagina. The condition of both patients was very low, due to persistent hemorrhages, and particularly deplorable owing to the unbearable odor of the ulcerating necrotic surfaces. In both cases, the usual means of treatment had been conscientiously employed for several months, but had failed to bring the slightest relief. The acetone treatment, on the other hand, completely overcame both discharge and stench and reduced the hemorrhages to a minimum.

The enthusiasm with which original methods of treatment for cancer are usually published by their respective inventors stands in crying contrast to the late results as surveyed above, so that we have grown to look on new suggestions with a sort of suspicious reserve. I have, therefore, refrained from permitting the wish to be father to the thought and have, in this preliminary report, limited myself strictly to stating certain observations made with acetone in the treatment of the unbearable odor of inoperable carcinoma of the uterus. Incidentally, the effect of this treatment on the amount of discharge and hemorrhage has been noted. I have given the technic in detail so as to aid those who are willing to afford a fair trial to this new mode of treatment which seems to produce no untoward effect, but which has brought material relief to the patients treated.

I am greatly indebted to my associate, Dr. F. Hinchey, for his interest and assistance in carrying out these investigations.

MYXEDEMA

CAMPBELL P. HOWARD, M.D.

Outdoor Physician to the Montreal General Hospital,
MONTREAL, CANADA.

(Concluded from page 1333)

THYROID GLAND

The size of the gland may be difficult to determine owing to the associated fulness of the neck. In a very considerable number of cases, however, there is a distinct diminution in the size of the gland. In 61 patients of my series in whom the condition of the gland is noted it was atrophied or not palpable in 46 (75.4 per cent.), in 3 of whom it was previously hypertrophied. In the London series it was atrophied in 22 of 59 cases (37.3 per cent.), in 3 it was also previously enlarged. Hun and Prudden¹⁰ found that the gland was diminished in size in 78 per cent. of their cases. In the London series there were 4 patients in whom there was definite hypertrophy at the time of the examination, which, with the 3 in each of the London and American series, in which there was a history of previous enlargement, make a total of 14 patients with hypertrophy of the thyroid gland. *Apròpos* of this occurrence, Ord,³¹ in 1898, wrote

It appears to me probable that we shall recognize in the near future more and more the occurrence of a stage of hypertrophy of the thyroid gland with or without signs of Graves' disease, as an antecedent of myxedema. The enlargement of the thyroid in exophthalmic goiter is due partly to hyperemia and partly to change in the gland, which are apt in certain cases to determine proliferation of the epithelium surrounding the cells, such proliferation ending in the replacement of the true glandular structure by fibrous material and consequent destruction of the functions of the gland.

NERVOUS SYSTEM

The nervous system is next to the cutaneous system in degree of involvement. But it is rather a functional than an organic derangement, as only in a few cases are these symptoms due to organic changes in the brain and spinal cord. The chief characteristic is a slowness in the execution of all the nervous functions, due, according to Ord, to the condition of the skin which interferes with the natural exposure of the nerve terminals to stimuli from without, and hence a failure of the natural stimulation of the centers.

Cerebral Functions—Though the intelligence of the patient may be perfectly normal there is a large proportion of cases (37 in my series) in which there is a slowing of cerebration as to apprehension and thought. A prolonged interval may elapse before the nature of a question or command is grasped by the patient. A mental lethargy or somnolence may be present, so that the patient sits for hours at a time in the same position, taking no interest in his surroundings and evidencing no sign of mental or bodily activity. Charcot has likened this condition of apathy to the hibernation of the lower animals. Abnormal persistence in thought may be present.

The memory, especially for recent events, becomes impaired during the early stages. Impairment of memory was noted in 38 per cent. of my series, in 33 per cent. of Hun and Prudden's series and in 65 per cent. of the London cases.

Sleep, as a rule, is good, there may be an excessive somnolence (32 cases), especially in the daytime. In some cases insomnia may occur (14 cases) or the sleep may be disturbed by bad dreams or even actual night

terrors (7 cases). The disposition is usually placid, though irritability is not uncommon (13 cases). Periods of placidity may alternate with periods of irritability. There is often a morbid sensitiveness about the personal appearance with a strong desire for seclusion and a dislike for the presence of even the immediate members of the family. Various phobias may occur, especially agoraphobia or fear of open places (5 cases). There is a marked tendency to suspicion and self-accusation, the suspicion is not one of conspiracy or intent to harm, but the patient has a fixed idea that all the world is finding fault with him and regards him unfavorably. Some bemoan all their past sins, real or fancied. Morbid impulses were present in 3 patients of my series. Hallucinations and delusions of both sight and hearing, either alone or in combination, occur in many of the advanced cases (16 cases). Hallucinations of sight are most common. Exalted ideas may be present. Actual insanity occurs either in the form of acute or chronic mania, melancholia or dementia. Melancholia was present in 9 of my series, in 3 with a suicidal tendency. There was only 1 case of mania. The patients in 3 of 13 cases seen by Allen Starr²² were brought to him on account of some mental aberration. Cases of myxedema are to be found in nearly every insane asylum, such cases of insanity usually terminate in convulsions, coma and death.

SENSORY SYMPTOMS

Subjective—Abnormal subjective sensations are common. Most frequently there is chilliness or a great susceptibility to cold, as was present in 59 of 61 patients in my series (96.7 per cent.). It is very frequently described as a sense of a trickling of cold water on the skin, more especially down the spine. Further, patients are usually brighter and more comfortable in warm weather. Very commonly there is a sense of intense fatigue and languor on the slightest exertion (43 cases), so that the most trivial action assumes gigantic proportions and is dreaded by the patient. Various neuralgia pains in the muscles and joints occur. These were present in 29 cases of my series, in 2 of which they were localized to the thyroid region. Headache, especially occipital, is common (25 cases). Various paresthesiæ, as numbness, tingling, formication, itching, etc., are frequent and occurred in 30 cases. Other less usual symptoms are vertigo (14 cases), syncope (3 cases), dyspnea on exertion (20 cases), palpitation of the heart (9 cases) and dysphagia (11 cases).

Objective—Cutaneous sensibility, as a rule, suffers no actual loss. Delayed sensation has been more commonly noted, and in a few cases to a remarkable degree, yet allowance must be made for the slowness of response to stimuli, owing to the mental hebetude present. In advanced cases actual anesthesia to touch and pain may occur, as was noted in 9 cases of my series. In another 3 cases there was merely hypesthesia. Hyperesthesia rarely occurs (2 cases). Hun and Prudden¹⁰ found cutaneous sensibility diminished in 21, retarded in 10, increased in 4 and normal in 35 cases.

MOTOR SYMPTOMS

Slowness of all the voluntary movements is very characteristic of the disease, and is rarely absent. There is often some clumsiness, especially in the performance of the finer movements, and there may be actual ataxia (12 cases). The gait is peculiar and almost characteris-

tic, being of a waddling, shuffling, lumbering nature, well described by Bramwell in the term "hippopotamus-like" (32 cases). Occasionally there is also an unsteadiness and staggering with a great tendency to fall, resulting in fracture of a bone or dislocation of a joint, as occurred with one patient in my American series.

Though actual paralysis is an accident, paresis of the various muscles is relatively common (34 cases). Weakness of the neck with falling forward of the chin on the sternum is often seen in adult myxedema just as in cretinism. Again, the head may fall backward between the shoulders with terrifying suddenness. There is a marked tendency to exhaustion after any prolonged or concentrated effort, and some patients are practically bedridden in the later stages of the disease, and even in the early stages find it impossible to walk a hundred yards or dress themselves without aid. In walking a quivering of the muscles may be seen, and actual tremor (3 cases) or muscular twitching (1 case) are not unknown. A case reported by Stewart³⁸ presented the interesting complication of tetany, and, as far as I know, is unique in literature. The superficial reflexes are sometimes diminished and in rare instances absent. The deep reflexes are usually stated to be normal, though Hun and Prudden¹⁰ found them abnormal in more than 50 per cent. In my series they were noted as normal in 11, exaggerated in 5 and diminished in 6 cases. The electrical excitability of the muscles was diminished in at least 60 per cent. of the cases of Hun and Prudden. In my series it was noted as normal in 4 and diminished in 3 cases.

SPEECH AND SPECIAL SENSES

Speech—Changes in the speech are very constant, and were present in 100 of 104 cases (96.1 per cent.) in the London series, in 104 of 107 cases (97.2 per cent.) in Hun and Prudden's and in 71 of 73 cases (97.2 per cent.) of my series. Slowness is the most marked feature, but articulation may be present to a slight degree. Actual aphasia is of rare occurrence. The speech is best described as deliberate, hesitating and monotonous. There is an apparent difficulty in getting words out of the mouth, as they stick at the lips and are only enunciated with a visible contortion of the mouth and lips. Yet, in spite of this difficulty, the patient is often garrulous and will talk for hours in the face of repeated interruptions. The quality or timbre of the voice is characteristically hoarse, thick, nasal or leathery as was noted in 39 of our patients. There is probably a nervous as well as a mechanical cause for this change in the voice and speech, the mechanical cause being the swollen condition of the mucous membrane of the larynx, soft palate, mouth and tongue, the nervous element being the slowness of cerebration and execution of voluntary effort.

Vision—In a small proportion of the patients (16) dimness in the acuteness of vision was noted. Exophthalmos has been observed in the early stages, probably in association with a pre-existing Graves' disease. The examination of the fundi is usually negative, but there was optic atrophy in 3 of our series—neuroretinitis in 1 and sclerosis of the retinal vessels in 1. In a case of a young girl recently married, reported by Moffitt,¹⁷ there was atrophy of the nasal side of both optic discs, with limitation of color vision in the temporal halves of both fields. Optic atrophy has been ascribed by Uthoff and Moffitt to a possible association of an hypertrophy of the hypophysis cerebri.

Hearing—Hearing was impaired in 25 of 32 cases (78 per cent.) in which this point was noted in my series. It may be unilateral or bilateral. In some it may be simply coincident, but in the majority it is due to the disease. Hammond⁹ thought it might be caused by an actual diseased condition of the auditory nerves. Subjective auditory sensations, as tinnitus aurium, occurred in 6 of my patients and in the patient in Case 7 to a distressing extent.

Taste—Taste is often impaired (9 cases). Perverted subjective sensations are also common (6 cases). A bitter, acid or metal-like taste may be constantly present. Taste was noted as normal in another 6 cases.

Smell—Smell may also be impaired or perverted, as occurred in 7 out of 13 patients in whom this point was noted. Hun and Prudden¹⁰ found that taste and smell were impaired in about 33 per cent. of their series.

CIRCULATORY SYSTEM

Temperature—The temperature is nearly always 1 to 3 degrees (Fahrenheit) below normal when the disease is well advanced. In the early stages it may be normal or even one to two degrees above. In a well-defined case a temperature of 98 to 99 F° is an indication of fever. In 75 cases in my American series it was normal in 15 patients, subnormal in 58, slightly febrile (99.4) in one in whom the symptoms of myxedema had followed those of Graves' disease, and decidedly febrile (102.5) in the patient with acute myxedema reported by Osler.³⁰ Of the subnormal cases there were 6 patients in whom it ranged between 93 and 96 and 15 between 96 and 97. In the London series there were 10 patients in whom the temperature ranged between 93 and 95. Hun and Prudden¹⁰ reported a subnormal temperature in 90 per cent. of the cases and one case in which the temperature fell to 66 before death.

Pulse—The pulse can be said to have nothing very distinctive, though in the majority of the cases it is slow and small or weak. Thus it was found to be below 80 to the minute in 35 and between 80 and 100 in 18 cases. In 3 of my cases the pulse was rapid, in two of which there was an associated enlargement of the thyroid gland, and in the third the course was one of acute myxedema.

Blood Pressure and Blood Vessels—The blood pressure was said to be below normal in 3, normal in 1 and above normal in 2 cases. The heart was found to be normal in 54 per cent. of the London series and in 40 per cent. of Hun and Prudden's cases. The latter found cardiac hypertrophy, aortic accentuation or a reduplication of the heart sounds in a considerable number of cases. In long-standing cases the heart is said to become weak from myocardial degeneration. It is important to remember that in these cases the cardiac degeneration does not improve as rapidly under thyroid treatment, as the general condition and an unusual effort may lead to sudden fatal syncope. Cases of this accident have been reported by John Thomson and Murray. The condition of the heart and vessels was not specially studied in my series. In 2 cases, however, cardiac hypertrophy was noted. There is no special tendency to arteriosclerosis, it was noted only once in my series. The capillaries on the face are usually dilated.

Blood—The blood shows usually early in the disease a mild secondary anemia, with consequent slight pallor of the mucous membranes. This disappears as the general condition of the patient improves. Hun and Prudden¹⁰ found that in about 70 per cent. of 17 cases there

Albumosuria—This occurred in one of my series, a case reported by Fitz,³⁵ in which from 25 to 12 per cent of albumin was demonstrated by the usual tests von Jaksch has also reported a similar case

Sugar—Lorand, in his recent monograph on glycosuria, points out that in myxedema, unlike exophthalmic goiter, diabetes is a rarity. A few cases have been reported in which a true diabetes mellitus occurred in the course of the disease. In 1895 Ewald³⁹ reported the history of a woman, aged 55, in whom a cure of the myxedematous symptoms by thyroid extract was followed by a mild glycosuria. In my series in one case reported by Osler,³⁰ in 1899, and previously referred to, there was a glycosuria complicating acute Graves' disease associated with myxedematous symptoms.

In infantile myxedema, diabetes has also been reported. Gordon⁴⁰ has published the histories of two brothers who were congenital cretins, in whom glycosuria developed and was benefited by the administration of thyroid extract. Strasser,⁴¹ also of America, has more recently reported a remarkable case of a congenital cretin who, after 4 weeks' intermission from thyroid treatment, developed a marked polyuria and glycosuria, with all the symptoms of diabetes mellitus.

It must also be recognized that glycosuria may in rare instances develop after the prolonged or excessive use of thyroid extract, when a condition of hyperthyroidism, analogous to that of exophthalmic goiter, may occur. Bottman found that 55 per cent of 20 patients with maladies other than myxedema developed a temporary glycosuria under the experimental administration of thyroid extract. On the other hand, Scholz, among 100 cases of cretinism, was unable to produce by thyroid administration a single case of even alimentary glycosuria. What is the significance of diabetes occurring in the course of myxedema? Pineless and Strasser both point out that in the course of myxedema functional or even anatomic changes in glands other than the thyroid, as the pancreas, for example, may supervene.

DIAGNOSIS

The diagnosis of myxedema can almost be made at a glance, the clinical picture being pathognomonic. The solid edema with the characteristic facies, the condition of the skin and the hair, the mental hebetude, the slowness of thought, speech and action, the subnormal temperature, all form a train of symptoms that can not be mistaken for anything else.

OBESITY

If the condition be thought to be one of obesity, the therapeutic test of the exhibition of the thyroid extract can be resorted to.

BRIGHT'S DISEASE

Three of the cases in my series were mistaken for this. In chronic nephritis the edema is in the dependent portions of the body and is determined by gravitation, or it appears where the tissues are loose, further it pits markedly on pressure. The skin is thin and smooth and glossy. The complexion is pale in striking contrast to the hectic flush of myxedema. Lastly, the urine always shows signs of more or less serious renal disorder.

TROPHEDEMA

Trophedema or "dystrophie edémateuse" may offer more difficulty. This condition has been well described

by Meige,⁴² Rapi,⁴³ Hertoghe⁴³ and other French clinicians. It is characterized by the appearance of a white, firm, painless edema occupying one or more segments of one or both of the upper or lower limbs (preferably the latter), persisting throughout life without appreciable prejudice to health. It may be familiar, hereditary or even congenital. Sometimes it occurs sporadically. Occasionally there is disturbance of sensation. Trophedema is probably of nervous origin and is analogous to muscular dystrophy. In America, Ruhräh⁴⁴ reported the case of a girl with myxedematous-like swelling, which the author now believes can be best described as trophedema.

DERCUM'S DISEASE

Dercum's disease,⁴⁵ *adiposis dolorosa*, can be distinguished, first, by the presence of large, irregularly distributed, fatty tumors which are painful and very tender, secondly, by the sensitiveness of the nerve trunks, and, thirdly, by the reaction of degeneration on electrical stimulation of the muscles. The absence of sweat, the headache and the mental changes simulate myxedema very closely.

PERNICIOUS ANEMIA

Myxedema has been mistaken for pernicious anemia, owing to the prostration, diarrhea and mental lethargy. The absence of the characteristic blood picture and the chronicity of the course should clear up the diagnosis.

COURSE OF DISEASE

The course is generally slow and progressive, often lasting for years. The average course for cases in my series was 5 years and 9 months. Twenty-five lasted 10 years or more, the longest case being 15 and 16 years, respectively. Murray found that the average duration in 248 women was 7 years and in 32 men nearly 6 years. Sometimes, even in the absence of thyroid treatment, periods of improvement occur, suggesting an arrest of the disease.

MODE OF DEATH

In a certain number of cases death is the direct result of the myxedema either from general physical or nervous exhaustion, severe anemia, coma or mania. In a few cases cerebral or cerebellar hemorrhage has been the cause of death. The majority of patients, however, die from some intercurrent affection as tuberculosis, pneumonia, nephritis or pericarditis. Hun and Prudden⁴⁶ found the cause of death to be exhaustion and pericarditis, each, in 1 case, coma in 6, and pneumonia in 4 cases. In my series there were 10 deaths, of which the mode was not stated in 2, coma in 2 cases, asthma, sudden syncope, pneumonia, purulent bronchitis, edema of the larynx, each, in 1 case, and glycosuria, melena and mania in another case.

TREATMENT

GENERAL HYGIENIC

An important element in the treatment is the maintenance of body warmth, which is best secured by moving to a warm climate and by the wearing of warm clothes. The bowels must be regulated and a good, nutritious diet provided.

MEDICINAL

Until 1893 a great many different drugs were advised, and, as is always true when such is the case, none of

³⁵ Berl. Klin. Wochenschr. 1895 xxxii.

them were of especial value. Various tonics, as iron, quinin, hypophosphates were tried. Diuretics and diaphoretics were also used. Jaborandi and pilocarpin given over a long period of time have in some cases proved of benefit, depending, according to Davies,⁴⁰ not on their action on the skin, but on their tending to increase the secretion of the thyroid gland. Nitroglycerin and a host of other remedies had their day.

THYROID THERAPY

Byrom Bramwell⁴¹ says it is no exaggeration to say that the cure of myxedema by thyroid treatment is one of the greatest therapeutic achievements of this or of any other age.

As early as 1883 thyroid grafting was performed by Kocher, and later by Bucher, by transplanting the gland of a sheep into the tissues or body cavities of the patient. But it was found that the gland was soon absorbed. In 1890 von Eiselsberg noted that the transplantation of the thyroid gland from an animal to a patient would prevent the development of cachexia strumipriva in cases in which a complete thyroidectomy had been performed. In the same year Victor Horsley independently of von Eiselsberg suggested the procedure for a patient suffering from myxedema. But all met with the same fate until MacPherson on one occasion succeeded in transplanting the gland of a sheep into the subcutaneous tissues beneath the breast where it became vascularized and functionally active, so that the patient was free from all symptoms three years later. This method is unquestionably the ideal treatment, and Victor Horsley has recently advocated its trial in cases of postoperative myxedema, having previously instituted a course of thyroid therapy until all the symptoms have disappeared, when the transplantation can be attempted with more hope of success. In 1891 Murray⁴² of Newcastle first used with great success hypodermic injections of the glycerin extract of the thyroid gland of the sheep. In the following year Howitz of Copenhagen, and Fox and Mackenzie of England found that the exhibition of the thyroid gland by the mouth was as efficacious. The gland may be given raw or lightly cooked in doses of one-eighth of a lobe to one lobe of the sheep's thyroid once a day. The liquid glycerin extract may also be used, of which 90 minims correspond to one gland, hence the dose varies from 3 to 20 minims. The next advance was the preparation of the dry or desiccated extract, which has been put up in powder, pill or tablet form. Of all the preparations the tablet is the most convenient and keeps better, hence is the most efficacious. Parke-Davis, Armour and other firms have their own tablets. The Burroughs and Wellcome tablets from England are probably the most reliable.

Rules for Administration.—The first thing to determine is the most suitable constant daily dose of the drug; this can only be done by trial and must be determined for each case. It is best to begin with a small dose (one five-grain tablet or two grains of the extract) once a day, and gradually increase in frequency and in amount until the symptoms begin to subside. This stage of the treatment has to be carried out with great care in all cases in which the disease has lasted for some years, in the aged and in those who show any indication of arterial or cardiac degeneration.

Murray⁴³ says: "The patient should be kept at rest in bed for a time so that as little strain as possible may

be thrown on the heart and arteries." Sudden death has been reported in such cases following sudden over-exertion (as occurred in Case 78 of my series). The duration of the first stage of the treatment should be from 6 to 12 weeks for the advanced cases. Any undue acceleration of the pulse, as an increase of from 10 to 20 beats a minute, indicates over-dosage. Further, a rise of temperature of one degree above normal, vomiting or purging are also danger signals of thyroid poisoning. Extreme prostration, headaches, sweating and irritability are some of the other indications of the toxic effect of the drug, which in many ways are remarkably similar to the toxic symptoms of exophthalmic goiter in which one also has a condition of hyperthyroidism.

In my series of 76 cases, over-dosage was noted 13 times. In one patient a very great intolerance to the drug was experienced, at first even one grain a day caused a marked systemic disturbance. After 6 to 12 weeks of this first stage the frequency of the dose may be reduced. The minimum dose has also to be determined by trial. Many find one tablet a day necessary, while others are free from symptoms with one tablet every two or three days. If the extract be discontinued for any time there is a return of the symptoms as occurred in 3 cases of my series.

Effects of Thyroid Treatment.—The first effect noticed is the rising of the body temperature to normal. Next there is a gradual or even sudden diminution in the subcutaneous edema with a consequent loss in the body weight. Loss of weight was noted in 24 of my cases, and varied greatly in different cases, in 12 patients it was 20 pounds or over, in 4 of whom there was a loss of from 35 to 60 pounds in from 3 to 16 weeks. Ord²⁵ believes that during the disappearance of the edema some important metabolism of a nitrogen-containing substance occurs. There is also a restoration of the secretion of the skin which becomes moist and soft and loses its harsh, dry, roughened character. Very frequently the old skin is desquamated in the form of large flakes until an entirely new epidermis is exposed. The hair begins to grow in the form of a fine thick crop over the scalp, pubes and axillæ. The menses return to their normal regularity and quantity. The urine is sometimes considerably increased in amount, as was noted in two of my patients, and the albuminuria and cylindruria disappear. The anemia, however, may not clear up, nay more may be increased and be accompanied by the appearance of a true edema of the feet. Both these, however, usually disappear in a few weeks when the patient gains his normal strength. With the physical improvement there is a corresponding improvement, *pari passu*, in the mental and nervous symptoms. In some cases actual insanity has been cured. The expression brightens, the mind becomes active and the patient begins to take an interest in his or her environment and will shortly return with zest to the daily routine of life. When such a change in the bodily and mental condition of the patient occurs in a few short weeks, one is almost forced to conclude that the day of miracles has not passed.

Parathyroid extract has been tried by Hutchinson⁴⁴ of London in myxedema without benefit, though in experimental work with dogs no myxedematous symptoms occurred unless the parathyroids were removed along with the thyroid glands. Protonuclcin and a

⁴³ Ibid 1896 I

preparation known as 'thyroid-collod' were tried in one case each, but without any apparent success

PROGNOSIS

The prognosis in the untreated cases is most unfavorable. Of 64 cases that were followed by the London committee actual recovery occurred only once in a case of two and one-half years' duration. Hun and Prudden¹⁰ found only 2 cases reported to have ended in complete recovery without treatment, and in both the diagnosis was questionable.

In 2 cases reported by Kohler due respectively to syphilis and actinomycosis of the thyroid gland the patients have recovered under potassium iodid. In but few diseases has the outlook been so materially altered by the discovery of a specific drug, as has myxedema by the introduction of the thyroid treatment. Formerly the course was progressively downward and the ultimate termination was invariably lethal. Since the introduction of thyroid therapy, however, if treatment be commenced early and if there be no complications life should not be appreciably shortened. In severe cases of long duration in which the stage of shrinking in the gland has far advanced the outlook is not so good. Advanced cardiac or arterial degeneration is a source of great danger and thyroid treatment has in such cases been followed by death. If cylindruria or albuminuria or both persist in the urine after thyroid treatment, the prognosis depends on the extent of the kidney involvement.

In my series of 100 the result was given in 95 cases. It was thought better for the sake of comparison to divide the cases into two groups. The first group includes the cases treated by medical means before the introduction of the specific therapy, and the second the cases treated since the value of thyroid extract has been appreciated. In Group 1 there are 19 patients with 5 deaths, 10 unimproved and 4 said to be improved. The mortality was therefore 26.3 per cent. In Group 2 there were 76 patients with 5 deaths, 2 unimproved, 9 improved, and 60 cured. It is but fair to add that of the 5 patients who died, in one the diagnosis was made too late for treatment, a second had acute myxedema, a third showed tuberculosis of the adrenals at autopsy and a fourth died from a sudden syncopal attack during the thyroid administration. In only one case did the patient succumb after a prolonged treatment of four months. It would seem permissible therefore, to omit the first two of these cases, making 3 deaths in 72 cases or a mortality of 4.1 per cent, a rather remarkable drop from 26 per cent of the first group. Of the 2 unimproved cases, no data were given in one case and in the second the patient was treated for but six weeks with a preparation which was in all probability not the thyroid gland.

Of the 9 patients who were reported improved, one was treated by homeopathy, two were reported before any marked result could be expected, a fourth was well physically but not mentally. Of the remaining 5 either the data are scanty or the diagnosis seemed more or less questionable. Sixty patients out of 76 (79 per cent) were completely cured.

SOME PERSONAL EXPERIENCES IN THE USE OF ELECTRICITY IN OPHTHALMIC PRACTICE *

W. FRANKLIN COLEMAN, M.D., M.R.C.S., ENG.

President of and Professor of Ophthalmology in the Postgraduate
Medical School
CHICAGO

This report will be limited by request to the use of the galvanic and the form of alternating current known as the sinusoidal. That the subject of electricity in ophthalmic practice has received scant attention appears from a statement by the secretary of this section, Dr. Bulson: "For several years the subject has received no consideration. In 1898 Dr. Starkey read a paper on 'The Use of Galvanism in Pterygium,' and Dr. LeMond on 'The Value of Faradism in Choroiditis.' Since then nothing has been presented except some papers on the galvanic cautery and the magnet."

It is probably safe to say that there is no remedy which causes so varied physiologic manifestations and therapeutic results as electricity. By proper selection of modality, current strength, tension, polarity, length and frequency of application, etc., stimulation or sedation of the nervous and vasomotor systems, muscular contraction, decomposition and destruction of tissue, changes in nutrition and so forth may be produced. This "proper selection" requires a fair working knowledge of the physics and electrotherapeutics of the agent. Ranged on the side of "working knowledge" will be found those (conspicuously neurologists) who are securing recoveries by electric agencies, and have an enlightened faith in still greater future conquests, while, on the side of those who lack this knowledge, are conspicuously ophthalmologists who frankly admit this lack, neglect almost completely the use of electricity, and look askance at electrotherapeutics as the real means of recovery from disease which may have previously resisted the classically authoritative drug habit, and prefer to attribute the result to suggestion, coincidence or the bogey man.

Of all the modalities, galvanism furnishes the greatest variety of useful application to the eye as well as the rest of the organism, while, with the possible exception of radiotherapy, it requires the most skill for its safe and successful administration.

For the most part I have used electricity in chronic cases which are very intractable or usually considered not amenable to medication. In order that results may be properly referred to the current, the diagnosis, when possible, has been confirmed by confrères, other treatment avoided, and in several instances patients had been treated without success by the usual approved methods for long periods.

The cases embraced in this paper are taken from my records, without selection, except to include those treated for a sufficient time to warrant a fair conclusion as to the possibilities of the remedy. For the sake of completeness brief mention will be made of cases previously reported.

A word in regard to the nature and selection of the current used, and the technic of its application.

Previous to 1890 the galvanic battery of zinc-carbon elements, excited by a solution of potassium bichromate, was used, and since then the Edison street current, controlled and measured by the rheostat and meter of the ordinary wall plate.

* Read in the Section on Ophthalmology of the American Medical Association at the Fifty-seventh Annual Session, June 1906.

Epileptic Colonies.—The epileptic colony is a success. It has been shown to be a great public economy, the fruit of good statesmanship.—H. T. Patrick, M.D. in *Charities and the Commons*.

The alternating or sinusoidal current has been taken from a No 2 Victor transformer, using from 30 to 35 measured volts and a quantity estimated at 5 milliamperes. As the heat meter is not applicable to so small a quantity, it was thus estimated. With a force of 30 volts taken from the direct current, and the electrodes placed on the lids and the nape of the neck, the meter registered 5 m a, hence, with the same voltage from the alternating current and the same resistance the current is 5 m a.

PHYSICAL CHARACTERISTICS OF THE GALVANIC AND SINUSOIDAL CURRENTS

The maximum voltage of the No 2 Victor transformer is 70, and the milliamperage probably 1,000. The maximum speed is 2,800 revolutions a minute, and the alternations 5,600. While the current alternates, the sinusoidal wave is unbroken or continuous. Figure 1 represents the wave, Figure A, the galvanic.

In the absence of any tracing of the wave from the dynamo, I am not convinced that it is perfectly sinusoidal. Still, it is probable that a similar therapeutic effect may result from a wave that lacks its perfect symmetry. The galvanic current is used when its electrolytic property is desired to separate chemically the elements of a pathologic body, and when its polarity may be utilized as a sedative or a stimulant to the muscular, vascular and nervous tissue. For example, in consecutive optic atrophy galvanism is especially indicated, on account of the existing exudates, while in primary atrophy I much prefer the alternating current, as it ap-

Fig. A

pears to be more stimulating to the nerve the greater reaction of which is evident by the more intense light flash produced.

This can be shown by comparing a thirty-volt current from the dynamo with a thirty-volt galvanic current. The former is not unpleasant and causes a brilliant mosaic of dark and light, while the latter causes no phosphenes unless the current is interrupted and the burning is so intense that it can not be endured for more than a half minute.

The almost universal opinion that the alternating current has no electrolytic effect seems at least doubtful. A current of thirty volts causes as much decomposition of water as one of 5 m a from the galvanic, and potassium iodid in solution is readily decomposed, although with an equal amount of discoloration at each pole.

Since the exposure of the eye to the static, high-frequency, x-ray or faradic current causes no phosphenes, such currents probably have very secondary if any value in optic atrophy. The technic is as follows except when otherwise stated. Galvanism is generally applied with a large positive pad, 3x4 inches (to prevent smarting) to the nape of the neck and the negative pads to the closed lids for ten minutes daily, with a current of from 5 to 10 m a generally the latter. Since changing a Schulmeister (German) motor for a Victor (Chicago) only 3-5 m a have been used as the limit of tolerance. The electrodes of the sinusoidal are simi-

larly placed and from 30 to 35 volts can be tolerated, used for ten minutes daily.

Fourteen cases are fully reported in the *Annals of Ophthalmology*, July, 1898, and are omitted here.

CASE 15—Central retinitis, unimproved.

CASE 16—Paresis of r inferior and internal recti and of the sphincter pupillae. Recovery.

Patient—Feb 11, 1902 W F S, aged 35 clerk. Seven weeks previously he lost consciousness for four days during which time the right arm and leg were paralyzed. He then recovered consciousness and the use of the arm and leg. Three weeks later diplopia was noticed this was increased by looking to the left and down. R hypertropia, 5°, exotropia, 15°.

Treatment—Interrupted galvanic current 5 m a negative pole to lids, positive to neck, for ten minutes daily.

February 20 exota 8° P hyperta 3° April 2 exota 1°, R hyperta 2° April 26, orthophoria. Binocular field of fixation normal.

CASE 17—Amblyopia exanopsia R E V improved from 6" to 2.

Patient—April 12, 1902 J P S aged 37 printer. The right eye has diverged since childhood. V R F is now about the same as it has always been, he can see the tips of the fingers at 6". Fundus appears normal.

Treatment—The sinusoidal current to the eye ten minutes daily. Feb 12, 1903, he can distinguish thumb from fingers at 6". He is much pleased with the result as he can now see objects approaching from the right side, which enables him to get about the streets more safely.

CASE 18—Bluish white atrophy of left optic nerve, slight improvement from light perception.

Fig. 2—Case 10 Feb 7 1903

CASE 19—Retinitis pigmentosa P E —100 15°=20 80, improved to 20/40 L E, —125 16°=20 80 not improved (Fig 2).

Patient—Jan 20, 1903 Dr A B, aged 48 had good sight until an attack of measles in childhood since then night blindness has prevented him from going out in the evening and vision has been steadily failing. During the past seventeen years reading or fatigue caused a pain from the frontal to the occipital region, which glasses have considerably relieved. Fundi: Bars and plaques of pigment infiltrated along the peripheral retinal vessels. Family history good. No history of consanguineous marriage.

Treatment—Sinusoidal current to the eyes daily. On March 2, 1903, there has been no pain in the eyes since treatment.

CASE 20—Amblyopia exanopsia P I improved from 20/120 to 20 80.

CASE 21—Sequelae of specific relapsing iritis. V P I improved from ability to count fingers at 10 to 20 200 I I from light perception to 20/70.

Patient—Feb 2 1904 A N N aged 42.

History—He had a chancre two years ago in May, 1902 five months later the left eye was attacked with iritis and seven months later the right. Vision had been good previous to the attacks. He was under the care of an oculist for five months beginning a week after the attack in the left eye. Hydrargyrum and potassium iodid were prescribed by the oculist. Iodid of potassium up to the 4th day.

with the eye br left he

Second Attack—This occurred August, 1903, in the right eye, and continued two months without treatment. Vision has remained as at present during the past three months. R. E. V = counting fingers 10', L. E. has light perception. Under atropin Pupil of R. E. 3 mm, pupil of L. E. 2 mm. Fleecy opacities in each vitreous. Retinal vessels and discs invisible in fixation at 6" the left eye diverges.

Treatment—Galvanism ten minutes daily, the negative pole to the nape of the neck and the positive to the lids.

March 7, 1904 R. E. V = 12/200, L = 20/200

April 4, 1904 R. E. V = 15/200, L = 15/120 The sinusoidal current to the eyes. Galvanism discontinued.

April 19 R. E. V = 15/120 Discontinue sinusoidal current to the eyes and apply vibratory pneumatic massage with eye cups to eyes daily for five minutes.

May 2 Vision the same. Discontinue massage and apply the high frequency current from coil and Oudin resonator with vacuum electrodes to eyes daily for ten minutes.

May 13 Vision remains the same. Discontinue the high frequency current and apply galvanism Dionin 5 per cent daily for five days, then omit it for two days, and repeat.

Oct 6, 1904 R. E. V = 20/200, L. E. V = 20/70

CASE 22—Double optic atrophy, probably of cerebral origin. V. R. E. improved from light perception to 20/67 V. L. E. from 20/120 to 20/20

Patient—Oct. 3, 1903 L. W., aged 12, school boy, suffered from very severe headache, vomited about twice a week and was very delicate from the age of five to ten. He has been in good health during the past two years. On returning to school September 9 he noticed that he could not see figures well on the blackboard, and for a week past has had to read with his book very near his eyes.

Fig 3—Case 22 April 25 1904 White — blue — —, red

Examination—Skiascopy R. E. +1.00, L. E. —0.50. Ophthalmoscopy R. E. very white marginal band with gray center of disc, vessels normal. L. E. opaque white disc, white atrophic choroidal patch to the nasal side of disc and two-thirds its size, vessels normal. (Fig 3)

Treatment—Sinusoidal current

October 23 R. E. V = Light perception, L = 20/80

November 20 R. E. counts fingers excentrically at 6", L. E. V = 20/80

Jan. 7, 1904 R. E. V = 15/200, L. E. V = 20/30

February 4 R. E. V = 20/120, L. E. V = 20/20

March 7 R. E. V = 20/80, L. E. V = 20/20

April 25 R. E. V = 20/70, L. E. V = 20/20 The papillae appear as white as when first examined. Treatment discontinued.

Feb 13, 1906 R. E. V = 20/50, L. E. V = 20/20

CASE 23—Xanthelasma electrocuted

Patient—Jan 18, 1904 Mrs. A. R. J., aged 37

History—Four years previously three yellow patches appeared on the lids, one below the right inner canthus, one below and one above the left. They are at present $\frac{1}{8}$ " by $\frac{1}{4}$ " in size.

Treatment—Hypodermic cocaine. Negative galvanic needle beneath the left upper patch, 3 m. a., gradually increased to five for four minutes and this repeated with the needle at right angle to first insertion. There was no pain.

January 30 Patch absent, a small crust present. Needle used as above on the remaining patches.

February 20 and April 21 Needle again used

May 21 Patches absent

CASE 24—Tobacco and alcohol amblyopia. Double optic atrophy. V. R. E. improved from 6/100 to 9/100 V. L. E. improved from 4/100 to 9/100

CASE 25—Optic atrophy from wood alcohol. V. R. E. $\frac{1}{2}$ /100, L. E. 1/100, decreased to ability to count fingers.

Later this patient, supposed to suffer from inhalation only, says he drank wood alcohol, supposing it was ordinary alcohol.

CASE 26—Impaired vision and headache relieved.

CASE 27—Intraocular hemorrhage in right eye, with only light perception, unimproved by three months' previous treatment. Recovery, with normal vision.

History—May 22, 1904 Dr. A. S., aged 39, was taken ill on March 4, 1904, losing consciousness, and on recovering it two days later found that he could only distinguish light. His memory, hearing, and sight remained bad for a week, and then he recovered. Ten days later he had pain in the left eye in the evening, and the next morning both eyes became again blind. Nine days after the first attack the three oculists consulted agreed in a diagnosis of hemorrhage in each vitreous. Later he consulted four oculists, three of whom agreed with the above diagnosis, while one considered the case choroiditis, with exudates. Under treatment the left eye recovered normal vision, while the right eye has only had light perception since the second hemorrhage.

Previous treatment consisted of pilocarpin injections, atropin and dionin, and subconjunctival injection of cyanid of mercury (once). Electricity had not been suggested. The consultants agreed that the vision of the right eye is hopeless.

Fig 4—Case 23 Feb 10 1905 White —, blue — —, red

lessly lost. Leucocythemia and acute toxemia had been diagnosed.

Examination—R. E. has only perception of light, with dilated pupil the mirror gives no fundus reflex. L. E. V = 20/20, notwithstanding a considerable amount of fluffy vitreous opacity.

The patient was advised to try galvanism and referred to his oculist, who handed him over to me.

Treatment—Galvanism with cathode to right lids and current gradually increased from three to ten m. a., for ten minutes daily. After four days fingers could be counted to the right, and four days later in the whole field.

June 7 R. E. V = 20/67

June 25 R. E. V = 20/40, temporarily. He now has an annoying diplopia with divergent strabismus, but is assured that this will disappear if vision becomes normal. In April treatment was discontinued.

September 4 R. E. V = 20/25

May 11, 1905 R. E. V 20/20, intermittently = 0.5 (S) at 12". There is no diplopia. Binocular fixation in reading. Convergence = 10 m. a.

Feb 14 1906 R. E. V = 20/20 fluently = 0.5 (S) at 14". Vision somewhat clouded by a considerable amount of dust and string opacities in the vitreous. The details of the fundus are distinctly seen and appear normal except as above stated. Advised to renew galvanic treatment.

CASE 28—Amblyopia (hysterical?) R. E. V = 20/200, improved to 20/25, L. 20/100 to 20/25

Patient—Feb 15, 1905 Mrs J F, aged 44, has never had good eyes

History—Five years ago, glasses +2.25 for distance and +3.50 for reading were prescribed. Her sight has been failing for nine years. She does not remember the time when she could read without a very good light. (Fig 4)

General Health—She has had more than a dozen voluntary abortions. In 1904 she had two miscarriages without severe hemorrhage, and without affecting vision. Three years ago her sight failed very much after the loss of her husband, by accident, and since then she has been subject to heat flashes and profuse sweating hourly in the day and often in the night, accompanied by palpitation.

R. E V = 20/200 + 1.75 + 0.50 180° = 20/200 better, L. E V = 20/100 + 1.75 = 20/100

Treatment—Sinusoidal current to eyes and general electrization with the auto-condensation couch ten minutes daily

March 2 R. E V = 20/100, slowly, L. E V = 20/30. The eyes feel stronger. The flashes, sweating, palpitation and nervousness are very much less.

September 21 R. = 20/50, L. = 20/25. This morning she lost the sight of the right eye for an hour.

Feb 10, 1906 R. E V = 20/25 - 2, L. = 20/25 +. At times she can not see to read, and again sees only the left side of words.

CASE 29—Paresis left internal rectus, improvement

CASE 30—Double specific choroiditis with vitreous opacities. R. E V 20/70, improved to 20/50, and asthenopia relieved. L. E V 20/20

Fig 5—Case 39 Feb 13 1901 White ———, blue ———; red ——— green ———

CASE 31—Right optic atrophy. No improvement. L. E V 20/33, improved to 20/20

CASE 32—Xanthelasma. Removed by electrolysis and excision

Patient—Jan 7, 1903 Mrs C, aged 36, has four yellow patches, two above and two below each inner canthus

Treatment—The negative galvanic needle, 5 m a., completely removed one patch 2 in diameter in one sitting. The current was turned on rapidly (without previous anesthesia) and the pain was so severe the patient would not consent to have even a hypodermic needle puncture for further electrolysis, hence the three remaining patches were excised under chloroform

CASE 33—Opacities in the vitreous. L. E V improved from 20/70 to 20/40 and epiphora relieved

CASE 34—Sequelae of iritis. V R. E counts fingers at 8, improved to 6/50. V L. E fingers at 3', improved to seeing fingers at 10

Patient—June 5, 1900 Mrs J B, aged 55, has had repeated attacks of iritis during the past eighteen months

Examination—R. E: Pupil semi dilated and irregular floating opacities in the vitreous and capsular opacity. L. E Vision failed years ago. There is a large capsular opacity. Pupil normal size

Treatment—Galvanism 5 m a ten to fifteen minutes daily. June 22 Twelfth treatment, R. E. V = 6/50. L. E V = fingers at 10"

CASE 35—Alopecia of the lids. Improvement

CASE 36—Amblyopia. Left eye. Vision improved from 20/120 and 3 00 (S) to 20/80 and 2.25 (S)

CASE 37—Asthenopia. Relieved by glasses and galvanism

CASE 38—Pterygium tenuis, right eye unimproved

Patient—April 25, 1901 P V, aged 29

Treatment—Bipolar galvanic needles were used under the pterygium with 4 m a for two minutes

July 18 The pterygium the same. The positive needle applied under the pterygium, 2" from the cornea, 2 m a for two minutes

August 8 Positive needle twice inserted under the growth with 2 m a for two minutes. This procedure repeated August 15

September 17 The pterygium appears the same as before the first needling

CASE 39—Optic atrophy and retinitis circumscripta. Vision in each eye 15/200, improved to 20/50

Patient—Dec 12, 1901 T L S, male, aged 54

History—His sight began to fail in February, 1900, when ill with fistula in ano, and it has gradually failed, so that for the last two months he can not read the paper

Examination—Fundus. R. E The disc is bluish white and blurred on the nasal edge. There is a wash leather colored stippling in the macular region

L. E The disc is similar to the right. There are white and red dots in the macular region and also two diameters of disc up and in a similar infiltration. Color vision. He can only distinguish blue (Fig 5). General health. The fistula

Fig 6—Case 41 Oct. 10 1901

was operated on and his health is now good. He is subject to chronic rheumatism

Urine Normal

Since a year ago last October he has smoked one half dozen cigars daily (more than usual) and chewed one ounce of tobacco daily up to July 1, and has not used it since. He does not take stimulants. One daughter died from tuberculosis and one from traumatic spinal meningitis. He lost two uncles from phthisis

Treatment—Sinusoidal current applied to the eyes daily

Jan 14, 1902: R. and L. V = 20/200. Mercurv and potassium iodid internally. Sinusoidal current continued

January 23 R. E V = 20/200. L. V = 20/120. He reads a letter now which he could not do when he began treatment

February 18 R. and L. V = 20/50 = 0.5" with reading glasses

CASE 40—Double amblyopia, ending in optic atrophy and blindness

CASE 41—Double primary optic atrophy. Vision improved from uncertain counting of fingers at 6" to ability to read and to write her letters

Patient—Sept. 3, 1901 Miss F G, aged 36, school teacher

History—Six years previously she became very nervous on account of her inability to secure a certain position and vision began to fail first in the left, then in the right eye. She noticed words run together and this was not relieved by glasses

Examination—Pupillary reaction to li. Tergence

normal She confuses pink and gray with green, and blue with red

R. E. Gray white opaque disc, reticulated at site of physiologic cup and sharply defined

L. E. Disc similar to right, but not reticulated Retinal vessels normal (Fig 6)

General Condition—A few weeks before the sight failed she was thrown backward from a cart and hurt her back very much, but retained consciousness Her memory is particularly good She is subject to sick headache and is very nervous Patellar reflex is normal

Family History—Her father died of nephritis at the age of 61 Her mother is 68 and healthy She has two brothers and three sisters living A brother, 33 years of age, commenced to lose sight at 30 and can not see to read An oculist whom he consulted diagnosed optic atrophy and was unable to state the cause.

Previous Treatment—Six years ago she was under the care of a prominent oculist for a year in his private hospital in Cincinnati He diagnosed optic atrophy and prescribed strychnin hypodermically, baths, general massage, nitroglycerin and general faradism

Vision did not improve and remained about the same as it is at present, that is, she can count fingers uncertainly with either eye at 6"

Treatment—Galvanism daily to eyes

September 12 R. E. V = fingers at 14', L. E. V = fingers at 12" She read the headlines of a paper for the first time in six years

September 30 R and L V = fingers at 24" Sinusoidal current substituted for the galvanic The patient at this

Fig 7—Case 41 Ap 11 S 1906 White — red and blue

date was exhibited at the Chicago Ophthalmological Society Dr Snodacker, who had recently studied four years in European eye clinics, remarked he had not seen so advanced a case of optic atrophy during that time

October 29 R. E. V = 1/80 = fingers 4, L. E. = 1/120 = fingers at 3

November 12 In fixation at 12" the left eye diverges

Jan 27, 1902 R = 1/30 L = 1/80

February 10 Vision the same For some time she has been able to select her own letters from the mail and to answer correspondents At this date her newly found faith transferred her to the care of the so-called Christian scientists

CASE 42—Amblyopia (hysterical) R and L V = 20 80 improved to 20/25

Patient—Dec 17 1904 M M male, aged 10 was referred to me by an oculist

History—He was sent from school two years previously on account of failing sight He had been treated for one year at an eye clinic but without improvement

Family History—His father and paternal grandfather died of apoplexy His mother died from exhaustion

Examination—R. Fundus Physiologic cup is three times usual size and the vessels emerge very near the nasal side of the disc

L. Fundus Similar to right The boy is exceedingly nervous The case has been diagnosed as hemeralopia without pigmentation but night blindness is not complained of and there is no degeneration of the retinal vessels The small field of

vision without optic atrophy is characteristic of hysterical amblyopia, as is also a frequent diplopia

Treatment—Sinusoidal current tri weekly

March 1 R. = 12/10, L = 5/100

April 20 R = 8/100, L = 6/100 The fields are concentrically contracted to 20°

June 24 R. = 14/100, L = 10/100

November 28 R = 14/100, L = 14/100 Repeat.

December 16 R. = 20/50, L = 20/67

Feb 15, 1906 R E = 20/30, L E = 20/30

April 7 R. or L V = 20/25

CASE 43—Traumatic optic atrophy V L E = light perception, not improved

SUMMARY OF CASES TREATED ELECTRICALLY

Optic Atrophy—Fourteen patients, 23 eyes In 5 eyes in which vision = light, 40 per cent were improved One to seeing hand movements and one to 20/67

In 18 eyes in which vision = form Sixty-four per cent were improved Four, 60 to 125 per cent, two, 300 per cent, three, 500 per cent, one, 1,500 per cent, two from seeing fingers to reading In six there was no improvement

Vitreous Opacities—Seven patients, 12 eyes In 5 eyes vision = light One improved to counting fingers at 6 inches, one was unimproved In 12 vision = form Ninety per cent were improved Seven, 40 to 100 per cent, one, 200 per cent, one, 1,100 per cent In one there was no improvement

Amblyopia—Seven patients, 10 eyes All were improved Four, 20 to 100 per cent, six 200 to 700 per cent

Sequelæ of Iritis—Two patients, 4 eyes All were improved One from light perception to 20/70, one, 100 per cent, two, 200 per cent

Intraocular Hemorrhage—One eye Vision improved from light perception to 20/20

Retinitis Pigmentosa—One patient, one eye Improved 100 per cent One eye was not improved

Retinal Thrombosis—One eye Vision was improved from fingers at 14' to 6/15 and 0 5 at 12 inches

Sequelæ Central Retinitis—One patient two eyes No improvement

Asthenopia—Three eyes Recovered

Xanthelasma—Two patients Recovered

Paresis of Ocular Muscles—Two patients One recovered and one was much improved

Alopecia of Lids—One patient, improved

Nictitation—One patient Recovered

Pterygium—One eye No improvement

The recovery of cases Nos 1, 2, 21, 27, 41, 14 and 22 deserve to be emphasized as phenomenal, especially since in all except the last two, the patients had been previously treated without improvement

Thus, contrary to the contention of the erudite and lamented Noyes, and "most oculists" (Burnett) electricity does seem to justify its claim to usefulness in ophthalmic practice

DISCUSSION

Dr LEARNT'S CONNOR, Detroit, said that in general, as an experimental affair the use of electricity in therapeutics has been disappointing Most busy men dislike to take up so much of their time as is required for this treatment When the first wave of electricity passed over the country Dr Connor fitted himself out and began the use of electricity with the old apparatus At present, with the use of the street currents and the improved apparatus for transforming them into any kind of current desired it ought to be possible to get more definite results He has had great satisfaction in using electricity, not for gross pathologic lesions but in the treatment of the muscular and functional disturbances of the eyes He explains

Dr. S. LEWIS ZIEGLER, Philadelphia, considered it very unfortunate that electricity, which is accomplishing so much in the field of general medicine, and particularly in neural therapeutics, is looked on with such skepticism by ophthalmologists. The few who employ it successfully are enthusiasts, while the many are ignorant, indifferent, or else are rank agnostics. He said that Dr. Coleman evidently belongs to the class of enthusiasts and that he had submitted a liberal array of facts to substantiate his position. While endorsing most of the observations, Dr. Ziegler differed somewhat in method. The two fold action of the galvanic current (1) physiologic, and (2) physicochemical, manifested as electrolysis and cataphoresis, should be borne in mind in any endeavor to explain the various electric phenomena observed and the therapeutic effects obtained therefrom. The anode or positive pole is oxidative, and should be applied to all inflammations, while the cathode or negative pole is stimulating, and should be used in atrophy. A notable exception to this rule is glaucoma, in which the negative pole should be employed. This rule can be modified as experience dictates. The current strength gives the best results when it is a fraction of farad, high and low amperage low. Dr. Ziegler generally uses from 50 to 75

[illegible]

perception to 20/70. A case of toxic amblyopia from inhalation of the fumes of wood alcohol was restored to almost normal vision and fields after a year's careful treatment. In glaucoma the negative pole will relieve pain and reduce the tension, while the positive will increase both. Dr Ziegler was able thus to relieve a patient suffering from an attack of acute glaucoma and to prepare her for operation in about ten days. Galvanization of the cervical sympathetic has also proved successful in this disease.

He has tried the sinusoidal current in retinitis pigmentosa and in optic atrophy, but is not overenthusiastic as to the results obtained. He is sure, however, that it has a future, which only needs to be developed.

Electrolysis is, of course, a most valuable therapeutic measure. In trichiasis it is the only successful epilating agent. The needle is placed at the negative pole and the neck pad is made the positive. It is valuable to shrink up small tumors. In trachoma the bipolar needles will give the best results. In ectropion and angioma Dr Ziegler prefers galvanocautic puncture. He has used corneal electrolysis for leucomata, for powder marks and for corneal ulcers with considerable success. He has modified Alleman's electrode by making the tip convex instead of concave and applying it directly to the surface without the intervention of a drop of mercury. Cataphoresis, or the driving of medicaments into the ocular tissues by the positive current, should prove to be a valuable measure. In a patient where a heart lesion contraindicated etherization Dr Ziegler enucleated an eyeball under a cataphoric application of 20 per cent cocaine for twenty minutes without the patient suffering much discomfort.

Dr Ziegler concluded by saying that the evidence should convince every careful and unbiased observer that electricity deserves a most honored position in ocular therapeutics.

DR. GEORGE F. KEIPER, Lafayette, Ind., stated that he has tried all kinds of eye electrodes and has found that the best electrode is the human finger. By passing the current through his own body and out through the finger to the patient's eye, the physician will not hurt himself or the patient and will avoid any prejudice the patient may have against the use of electricity.

DR. W. F. COLEMAN, Chicago, said that his cases were chronic ones and he wished to get electrolysis, which is not in proportion to the voltage, but to the milliamperage. In opacities in the vitreous, for example, he uses all the milliamperage the patient will stand, usually ten. Dr Coleman uses the negative pole in hemorrhage while Dr Ziegler uses the positive, but stated that results may be obtained with either pole because the current is low so that it makes little difference. In principle, however, the negative pole is used to dissolve tissue and exudates. In optic atrophy stimulation is desired and the negative pole is used. Dr Coleman agreed with Dr Connor that the time required is a disadvantage and that it is often difficult to get patients to continue the treatment sufficiently long. He said that it is impossible to give a prognosis of recovery, but that this applies to other methods of treatment as well, though the day may come when we can. Dr Coleman said that the most favorable cases of atrophy are traumatic which have not such a serious basis pathologically as tabes, for instance. He said that he considers Dr Keiper's suggestion as to the use of the finger a good one in many respects, but confessed that he does not wish to spend the time. He might have patients on three different currents at the same time and would not have fingers enough to go round. In regard to regulating the current, he said that the graphite rheostat is unreliable, one may turn on 5 milliamperes and return to the patient in 2 minutes and find that there are 10. He advised getting a metallic rheostat not made of German wire but of a combination metal which is much better. A correct meter is also indispensable.

Naming of Carbon Compounds.—Nitro is a prefix indicating the group—NO derived from nitric acid by abstracting OH, thus nitroethane C_2H_5NO , nitrobenzene $C_6H_5NO_2$, Glycerin trinitrate $(C_2H_5(NO_2))_3$, is often wrongly called nitroglycerin.—*Pharm. Rev.*, August, 1906.

TOXEMIA OF PREGNANCY *

W. M. JORDAN, M.D.

Gynecologist to Hillman Hospital
BIRMINGHAM, ALA.

The pernicious vomiting of pregnancy, acute yellow atrophy of the liver, and eclampsia, are generally grouped together as manifestations of the toxemia of pregnancy. While eclampsia is admittedly a toxemia, it seems unwise to class it with the other two conditions, from which it differs widely in symptoms, pathology, and prognosis, if not in other respects. For this reason it seems to me that eclampsia should be studied entirely apart from the other two types. I wish it to be understood, therefore, that wherever the term toxemia is used in the present article it refers only to the toxemia responsible for pernicious vomiting and acute yellow atrophy and not to eclampsia unless so stated.

The most pronounced lesion to be found postmortem in a case of toxemia of pregnancy is a degeneration and necrosis of the parenchyma of the liver. While this lesion is characteristic of the toxemia of pregnancy, it is not peculiar to it, since practically the same changes may occur in toxemias from other causes, the difference being in degree rather than in kind. For instance, an extreme degree of hepatic necrosis is brought about by phosphorus poisoning. Similar, though less pronounced changes may occur after chloroform anesthesia, as pointed out by Bevan and Favill¹ and demonstrated experimentally by Offergeld.² Muller's³ experiments go to prove that similar effects may follow the administration of ether and other inhalation anesthetics, though the tendency is much less marked than with chloroform. Acute alcohol poisoning has been known to produce fatal necrosis of the liver, as noted by Quinke.⁴ These are examples of hepatic necrosis caused by chemical substances. As an instance of a similar process due to a vegetable poison, Quinke mentions the occasional occurrence of liver necrosis as a result of mushroom poisoning. The liver changes in yellow fever consist of a degeneration and necrosis, not essentially different from that caused by the poisons mentioned above.

The experiments of Traube, quoted by Lusk,⁴ would appear to prove that necrosis of the parenchyma of the liver may be brought about by an excess of bile acids in the blood. This information must be accepted second-hand, if at all, since the reference to Traube's article is not given by Lusk. Traube's experiments might well be repeated with a view to confirming his results. If his observation is correct it throws light on some of the obscure deaths in coma following operations for common duct obstruction. It would also appear to offer a possible explanation of the pathogenesis of acute yellow atrophy of the liver occurring in males and non-pregnant females. It would be reasonable to suppose, for instance, that ordinary catarrhal jaundice, when occurring in an individual whose liver is excessively intolerant of the presence of bile acids in the blood may induce necrosis of such a liver in the same way as the various poisons already mentioned. This would be an example of hepatic necrosis due to the absorption and subsequent poisonous effect of a physiologic secretion. It will thus be seen that necrosis of the liver parenchyma
